#### Abstract

We solve a family of quadratic Diophantine equations associated with a simple kind of game. We show that the ternary case, in many ways, is the most interesting and the least arbitrary member of the family.

## 1. The Matching Games

An $(n, d)$-matching game $(n, d \geq 2)$ is a game in which the player draws $d$ balls from a bag of balls of $n$ different colors. The player wins if and only if the balls drawn are all of the same color. A game is non-trivial if there are at least $d$ balls in the bag. It is faithful if there are balls in each of the $n$ colors. A game is fair if the player has an equal chance of winning or losing the game. In this article, we only study the ( $n, 2$ )-matching games or simply the $n$-color games, leaving the study of the higher $d$ case to [10].

An $n$-tuple $\left(a_{1}, \ldots, a_{n}\right)$, where $a_{i}$ is the number of balls in the bag having the $i^{\text {th }}$ color, represents an $n$-color game. For $m \leq n$, an $m$-color game $\left(a_{1}, \ldots, a_{m}\right)$ can be regarded as the $n$-color game $\left(a_{1}, \ldots, a_{m}, 0, \ldots, 0\right)$. The only trivial $n$-color fair games, are the zero game $(0, \ldots, 0)$ and, up to permutation, the game $(0,0, \ldots, 1)$.

By considering the number of ways for the player to win the game, one sees that the $n$-color fair games are exactly the non-negative integral solutions of

$$
\binom{\sum_{i=1}^{n} x_{i}}{2}=2\left(\sum_{i=1}^{n}\binom{x_{i}}{2}\right)
$$

or equivalently,

$$
\begin{equation*}
F_{n}\left(x_{1}, \ldots, x_{n}\right):=\left(\sum_{i=1}^{n} x_{i}\right)^{2}-\sum_{i=1}^{n} x_{i}-4 \sum_{i \neq j} x_{i} x_{j}=0 \tag{1}
\end{equation*}
$$

The paper will be organized in the following way: We give a brief treatment of the 2 -color games in Section 2. The results there illustrate the kind of questions that we try to answer in the general case. In Section 3, we give a "parametric" solution to Equation (1). It is unclear, however, from this method which choice of the parameters will yield the fair games. We tackle this problem in Section 4 by giving a graph structure to the solutions. We show that the components of this graph are trees and give an algorithm for finding their roots. This yields all solutions recursively. Furthermore, we characterize the components containing the fair games. For $n=3$, we show that the graph consists of two trees with the nontrivial 3-color fair games forming a full binary tree. We then study what are the possible coordinates of fair games in Section 5. In Section 6, we establish some partial results concerning the asymptotic behavior of 3 -color fair games. We conclude the article with some odds and ends of our study in Section 7.

The following conventions will be used throughout this article:

- All variables and unknowns range over the integers unless otherwise stated.
- The cardinality of a set $A$ is denoted by $|A|$.
- For $\boldsymbol{a} \in \mathbb{Z}^{m}$, the (Euclidean) norm of $\boldsymbol{a}$ is denoted by $\|\boldsymbol{a}\|$. For $A \subseteq \mathbb{Z}^{m}$ and $k \geq 0, A(k)$ denotes the set of elements of $A$ with norm at most $k$. We define the height of $\boldsymbol{a}$ to be $\left|1+\sum a_{i}\right|$.
- For any integer $d$ and $\boldsymbol{a}, \boldsymbol{b} \in \mathbb{Z}^{m}$, we say that $\boldsymbol{a}$ and $\boldsymbol{b}$ are congruent modulo $d$, written as $\boldsymbol{a} \equiv \boldsymbol{b} \bmod d$, if $a_{i} \equiv b_{i} \bmod d$ for all $1 \leq i \leq m$.
- Denote by $\mathcal{S}_{n}$ and $\mathcal{F}_{n}$ the set of integral and non-negative integral solutions, identified up to permutations, of Equation (1) respectively. Elements of $\mathcal{F}_{n}$ are the $n$-color fair games. We often use an increasing (or decreasing) tuple to represent an element of $\mathcal{S}_{n}$. Denote by $\mathcal{C}_{n}$ the set of coordinates of $\mathcal{F}_{n}$.
- For any $n$-tuple $\boldsymbol{x}=\left(x_{1}, \ldots, x_{n}\right)$ and $I$ a subset of the indices, we write $\boldsymbol{x}_{I}$ for the tuple obtained from $\boldsymbol{x}$ by omitting the variables indexed by the elements of $I$. We write $\boldsymbol{x}_{i}$ for $\boldsymbol{x}_{\{i\}}$ and $\boldsymbol{x}_{i j}$ for $\boldsymbol{x}_{\{i, j\}}$, etc.
- Let $s(\boldsymbol{x})$ and $p(\boldsymbol{x})$ be the symmetric polynomials of degree 1 and 2 , respectively, i.e.,

$$
s(\boldsymbol{x})=\sum_{i=1}^{n} x_{i}, \quad p(\boldsymbol{x})=\sum_{1 \leq i<j \leq n} x_{i} x_{j}
$$

We often omit writing out the variables explicitly, so we write $s_{i}$ for $s\left(\boldsymbol{x}_{i}\right), s_{i j}$ for $s\left(\boldsymbol{x}_{i j}\right)$, etc. We understand $s \equiv 0$ on zero variables and $p \equiv 0$ on either 0 or 1 variable.

Thanks go to Jackie Barab from whom the second author first learned about the 2-color games ${ }^{1}$. We thank Bjorn Poonen for referring [7] to us. We would also like to thank Thomas Rohwer and Zeev Rudnick for bringing [3] and [11], respectively, to our attention. Finally, we thank Roel Stroeker and Michael Larsen for reading a draft of this article and giving us several valuable comments.

## 2. The 2-Color Games

As a warm-up, we analyze the 2-color games first. In this case, Equation (1) becomes $\left(x_{1}-x_{2}\right)^{2}-\left(x_{1}+x_{2}\right)=0$ and is easy to solve: let $m=x_{2}-x_{1} \geq 0$, and then $x_{1}=m(m-1) / 2$ and so $x_{2}=(m+1) m / 2$. This shows that

Theorem 1. The 2-color fair games are pairs of consecutive triangular numbers. In particular, $\mathcal{C}_{2}$ is the set of triangular numbers.

Using Theorem 1, a few simple computations tell us the number of fair 2-color games of norm bounded by a given number.

Corollary 2. For $k \geq 0$,

1. $\left|\mathcal{F}_{2}(k)\right|=[\sqrt{r(k)}]+1$. Hence $\left|\mathcal{F}_{2}(k)\right|$ is asymptotic to $2^{1 / 4} \sqrt{k}$.
2. $\left|\mathcal{C}_{2}(k)\right|=[r(\sqrt{k})]$. Hence $\left|\mathcal{C}_{2}(k)\right|$ is asymptotic to $\sqrt{2 k}$.

Here $r(k)=\left(-1+\sqrt{1+8 k^{2}}\right) / 2$ and $[x]$ is the largest integer $\leq x$.

## 3. Solving Equation (1)

It would be nice to know in advance that Equation (1) is solvable. The following simple observation tells us just that.

Theorem 3. There are infinitely many faithful $n$-color fair games.
Proof. Regarding the polynomial $F_{n}$ in (1) as a quadratic in $x_{k}$, we have

$$
\begin{equation*}
F_{n}(\boldsymbol{x})=x_{k}^{2}-\left(2 s_{k}+1\right) x_{k}+F_{n-1}\left(\boldsymbol{x}_{k}\right) \tag{2}
\end{equation*}
$$

Thus if $\left(a_{1}, \ldots, a_{k}, \ldots, a_{n}\right)$ is a solution then so is $\left(a_{1}, \ldots, b_{k}, \ldots, a_{n}\right)$ where $b_{k}=$ $2 s_{k}(\boldsymbol{a})+1-a_{k}$. In particular, if $\left(a_{1}, \ldots, a_{n-1}\right)$ is a fair game, then so are the tuples $\left(a_{1}, \ldots, a_{n-1}, 0\right)$ and $\left(a_{1}, \ldots, a_{n-1}, 1+2 \sum_{i<n} a_{i}\right)$. The latter game is faithful if $\left(a_{1}, \ldots, a_{n-1}\right)$ is. Since there are infinitely many faithful 2 -color fair games (Theorem 1), the theorem follows by induction on $n$.

[^0]Since the two roots of (2) sum to $2 s_{k}+1$, they can be expressed as $s_{k}+m+1$ and $s_{k}-m$ for some $m \geq 0$. Thus, solving

$$
\begin{align*}
\left(s_{k}+m+1\right)\left(s_{k}-m\right) & =F_{n-1}\left(\boldsymbol{x}_{k}\right)=s_{k}^{2}-s_{k}-4 p_{k} \\
2 s_{k}+4 p_{k} & =m^{2}+m \tag{3}
\end{align*}
$$

will solve (1) and vice versa. After adding $1+4 s_{i j k}^{2}+2 s_{i j k}-4 p_{i j k}(i, j, k$ pairwise distinct) to both sides of (3), the left-hand side factors:

$$
\begin{gather*}
\left(2 x_{i}+2 s_{i j k}+1\right)\left(2 x_{j}+2 s_{i j k}+1\right)=m^{2}+m+1+4 s_{i j k}^{2}+2 s_{i j k}-4 p_{i j k} \\
=m^{2}+m+1+2\left(s_{i j k}^{2}+s_{i j k}+\left\|\boldsymbol{x}_{i j k}\right\|^{2}\right) \tag{4}
\end{gather*}
$$

Equation (4) gives us a way to solve Equation (1): Denote by $J\left(\boldsymbol{x}_{i j k}, m\right)$ the righthand side of (4). Choose $\boldsymbol{a} \in \mathbb{Z}^{n-3}$ and $m \geq 0$ arbitrarily $^{2}$. According to (4), we can solve for $x_{i}$ and $x_{j}$ by factoring the odd number $J(\boldsymbol{a}, m)$ into a product two odd numbers. By (2), we can then solve for $x_{k}$ and hence obtain a solution of (1). Moreover, it is clear from the discussion above that any solution of (1) arises from such a factorization. For the record, we have
Theorem 4. Fix $n \geq 3$. For any $\boldsymbol{a} \in \mathbb{Z}^{n-3}$, $m \geq 0$ and $0 \leq b \leq c$ such that $J(\boldsymbol{a}, m)=(2 b+1)(2 c+1)$, the following are solutions to Equation (1):

$$
\begin{aligned}
& (b-s(\boldsymbol{a}), c-s(\boldsymbol{a}), b+c+1-s(\boldsymbol{a})+m, \boldsymbol{a}) \\
& (b-s(\boldsymbol{a}), c-s(\boldsymbol{a}), b+c-s(\boldsymbol{a})-m, \boldsymbol{a}) \\
& (-(c+1)-s(\boldsymbol{a}),-(b+1)-s(\boldsymbol{a}),-(b+c+s(\boldsymbol{a})+1)+m, \boldsymbol{a}) \\
& (-(c+1)-s(\boldsymbol{a}),-(b+1)-s(\boldsymbol{a}),-(b+c+s(\boldsymbol{a})+2)-m, \boldsymbol{a})
\end{aligned}
$$

Moreover, up to a permutation every solution of Equation (1) is in one of these forms.

There is a less tricky way to derive Equation (4). We give the idea here but leave the details to the reader. Equation (3) can be viewed as a curve on the $x_{i} x_{j}$-plane ( $i, j, k$ pairwise distinct). One can express the curve having an integral point by expressing that the corresponding quadratic in $x_{i}$ is solvable in terms of $\boldsymbol{x}_{i j k}$ and $d:=x_{j}-x_{i}$. The expression $1+4 s_{i j k}^{2}+2 s_{i j k}-4 p_{i j k}$ then flows out naturally.

Even though the method above solves Equation (1), it is unclear which choice of the parameters will produce fair games. For example, $J(2,3)=33$ does not produce any 4 -color fair game. We will take up this issue in the next section.

## 4. Solutions as a Graph

Starting from a solution $\left(a_{1}, \ldots, a_{n}\right)$ of Equation (1), we obtain another one by replacing $a_{k}$ with $b_{k}:=2 \sum_{i \neq k} a_{i}+1-a_{k}$ (see Theorem 3). This suggests that

[^1]we can view $\mathcal{S}_{n}$ as a graph by putting an edge between two elements of $\mathcal{S}_{n}$ if they differ at only one coordinate ${ }^{3}$. An immediate question would be: can we generate every fair game from some fixed game, say the zero game? In other words, is $\mathcal{F}_{n}$ connected as a graph? We have seen that $\mathcal{F}_{2}$ is connected (Theorem 1) and we will show that the same is true for $\mathcal{F}_{3}$. However, $\mathcal{F}_{n}$ fails to be connected for $n \geq 4$.

Let us begin with a crucial observation. For any $\boldsymbol{a} \in \mathcal{S}_{n}$ and any three pairwise distinct indices $i, j, k$, according to (4), for some $m \geq 0$,

$$
\left(2 s_{j k}(\boldsymbol{a})+1\right)\left(2 s_{i k}(\boldsymbol{a})+1\right)=2\left(s_{i j k}(\boldsymbol{a})^{2}+s_{i j k}(\boldsymbol{a})+\left\|\boldsymbol{a}_{i j k}\right\|^{2}\right)+m^{2}+m+1
$$

Since the right-hand-side is always positive, we conclude that
Proposition 5. For any $\boldsymbol{a} \in \mathcal{S}_{n}$, the numbers $2 s_{i j}(\boldsymbol{a})+1(1 \leq i<j \leq n)$ all have the same sign. In particular, the coordinates of an element of $\mathcal{S}_{3}$ are either all non-negative or all negative.

We define the sign of $\boldsymbol{a}$ as the common sign of the $2 s_{i j}(\boldsymbol{a})+1(1 \leq i<j \leq n)$. Note that it is the same of the sign of $s(\boldsymbol{a})+1$ since $\sum_{i<j} s_{i j}=\binom{n-1}{2} s$. Let $\mathcal{S}_{n}^{+}$and $\mathcal{S}_{n}^{-}$be the sets of positive and negative elements of $\mathcal{S}_{n}$, respectively. Since any two neighbors in $\mathcal{S}_{n}$ share $n-1$ coordinates, they must have the same sign, therefore

Proposition 6. Both $\mathcal{S}_{n}^{+}$and $\mathcal{S}_{n}^{-}$are a disjoint union of components of $\mathcal{S}_{n}$.
Our next result shows how height varies among neighbors.
Proposition 7. At most one neighbor of any vertex of $\mathcal{S}_{n}$ can have a smaller height. Moreover, any two neighbors must have different height.

Proof. Fix any $\boldsymbol{a} \in \mathcal{S}_{n}$. Let $\boldsymbol{b}_{k}=\left(a_{1}, \ldots, b_{k}, \ldots, a_{n}\right)$ where $b_{k}=2 s_{k}(\boldsymbol{a})+1-a_{k}$ ( $1 \leq k \leq n$ ) be its neighbors. Rearranging the coordinates if necessary, we assume $a_{1} \leq a_{2} \leq \cdots \leq a_{n}$.
Case 1: $\boldsymbol{a} \in \mathcal{S}_{n}^{+}$. Then for $k \neq n$,

$$
b_{k}=2 s_{k n}(\boldsymbol{a})+\left(a_{n}-a_{k}\right)+a_{n}+1>a_{n} \geq a_{k}
$$

so $s\left(\boldsymbol{b}_{k}\right)>s(\boldsymbol{a}) \geq 0$.
Case 2: $\boldsymbol{a} \in \mathcal{S}_{n}^{-}$. Then for $k \neq 1$,

$$
b_{k}=2 s_{1 k}(\boldsymbol{a})+\left(a_{1}-a_{k}\right)+a_{1}+1<a_{1} \leq a_{k}
$$

so $s\left(\boldsymbol{b}_{k}\right)<s(\boldsymbol{a})<0$.
This completes the proof of the first statement since in both cases we have $\mathrm{ht}\left(\boldsymbol{b}_{k}\right)>$ $\operatorname{ht}(\boldsymbol{a})$ for all but perhaps one $k$. The second statement follows readily from the fact that each $a_{k}+b_{k}$ is an odd number.

[^2]

Figure 1: A positive tree and a negative tree in $\mathcal{S}_{4}$

We say that a vertex of $\mathcal{S}_{n}$ is a root if all its neighbors have a greater height. We would like to point out that replacing height by norm in the definition of root will yield the same concept since Equation (1) can be rewritten as

$$
\begin{equation*}
\binom{s+1}{2}=\|\boldsymbol{x}\|^{2} \tag{5}
\end{equation*}
$$

Theorem 8. The components of $\mathcal{S}_{n}$ are rooted trees.
Proof. Proposition 7 implies that for any subgraph $H$ of $\mathcal{S}_{n}$, a vertex of maximal height in $H$ cannot have two neighbors in $H$. This shows that $\mathcal{S}_{n}$ must be acyclic. Moreover, every component of $\mathcal{S}_{n}$ has a unique vertex of minimal height. If not, take a path with two vertices of minimal height as endpoints. Since neighbors in $\mathcal{S}_{n}$ have different heights, the path has length at least 2 but then a vertex of maximal height in the path will have two neighbors, a contradiction.

Fair games are positive solutions of (1) and yet a positive solution, for example
$(-1,1,2,2)$, need not even represent a game. However, for any $\boldsymbol{a} \in \mathcal{S}_{n}^{+}$, a neighbor of $\boldsymbol{a}$ greater in height will have the different coordinate non-negative (see the proof of Proposition 7). Thus by going up in height along any branch, we see that

Proposition 9. Every component of $\mathcal{S}_{n}^{+}$contains fair games.
Similarly, by going down in height, we see that every component of $\mathcal{S}_{n}^{-}$contains solutions with all negative coordinates.

Our next goal is to locate the roots of $\mathcal{S}_{n}$. Once this is achieved, we will have an effective way of generating all fair games since each of them is connected to some positive root.

Proposition 10. Suppose $\boldsymbol{r} \in \mathcal{S}_{n}^{+}\left(\mathcal{S}_{n}^{-}\right.$, resp.) is a root and $i, j, k$ pairwise distinct where $k$ is the index of a maximal (resp., minimal) coordinate of $\boldsymbol{r}$. Then $\boldsymbol{r}$ is obtained from a factorization of $J\left(\boldsymbol{r}_{i j k}, m\right)$ for some $0 \leq m \leq B\left(\boldsymbol{r}_{i j k}\right)$ where $B\left(\boldsymbol{r}_{i j k}\right)$ is an explicit bound give in terms of $\boldsymbol{r}_{i j k}$.

Proof. We argue for $S_{n}^{+}$only. The proof for $S_{n}^{-}$is similar. According to (4), for some $m \geq 0$,

$$
\left(2 s_{i k}+1\right)\left(2 s_{j k}+1\right)=2\left(s_{i j k}^{2}+s_{i j k}+\left\|\boldsymbol{r}_{i j k}\right\|^{2}\right)+m^{2}+m+1
$$

Since $\boldsymbol{r}$ is a root, $r_{k}$ is the smaller root of Equation (2), i.e., $r_{k}=s_{k}-m$. And since $r_{k} \geq r_{\ell}(\ell \neq k)$, so $s_{\ell k} \geq s_{\ell k}+r_{\ell}-r_{k}=m$. Thus

$$
\begin{aligned}
(2 m+1)^{2} & \leq 2\left(s_{i j k}^{2}+s_{i j k}+\left\|\boldsymbol{r}_{i j k}\right\|^{2}\right)+m^{2}+m+1 \\
3 m^{2}+3 m & \leq 2\left(s_{i j k}^{2}+s_{i j k}+\left\|\boldsymbol{r}_{i j k}\right\|^{2}\right)
\end{aligned}
$$

That means $0 \leq m \leq B\left(\boldsymbol{r}_{i j k}\right)$ where $B\left(\boldsymbol{r}_{i j k}\right)$ expresses the larger root of the quadratic $3 x^{2}+3 x-2\left(s_{i j k}^{2}+s_{i j k}+\left\|\boldsymbol{r}_{i j k}\right\|^{2}\right)$.

Let us summarize how to find the roots of $\mathcal{S}_{n}$ : for each $\boldsymbol{a} \in \mathbb{Z}^{n-3}$, we compute the finite set consisting of those solutions given by the factorizations of $J(\boldsymbol{a}, m)$ where $0 \leq m \leq B(\boldsymbol{a})$. We then check which element in this finite set is a root. While Proposition 10 guarantees that every root of $\mathcal{S}_{n}$ can be found this way, our next result shows that we do have to check for every $\boldsymbol{a} \in \mathbb{Z}^{3}$.

Proposition 11. Every $(n-3)$-tuple of integers can be extended to a root in $\mathcal{S}_{n}$. More precisely, for any $\boldsymbol{a} \in \mathbb{Z}^{n-3}$, $n$-tuples

$$
\begin{aligned}
& \boldsymbol{r}_{+}:=\left(s(\boldsymbol{a})^{2}+\|\boldsymbol{a}\|^{2}, s(\boldsymbol{a})^{2}+\|\boldsymbol{a}\|^{2},-s(\boldsymbol{a}), \boldsymbol{a}\right) \quad \text { and } \\
& \boldsymbol{r}_{-}:=\left(-(s(\boldsymbol{a})+1)^{2}-\|\boldsymbol{a}\|^{2},-(s(\boldsymbol{a})+1)^{2}-\|\boldsymbol{a}\|^{2},-(s(\boldsymbol{a})+1), \boldsymbol{a}\right)
\end{aligned}
$$

are a positive and a negative root of $\mathcal{S}_{n}$, respectively.

Proof. First by Theorem 4, they are solutions corresponding to the trivial factorization of $J(\boldsymbol{a}, 0)$ (in the notation there, $b=s(\boldsymbol{a})^{2}+s(\boldsymbol{a})+\|\boldsymbol{a}\|^{2}$ and $c=0$.). Clearly, $\boldsymbol{r}_{+}$ is positive while $\boldsymbol{r}_{-}$is negative. The neighbor of $\boldsymbol{r}_{+}$obtained by varying its largest coordinate $s(\boldsymbol{a})^{2}+\|\boldsymbol{a}\|^{2}$ has an even larger coordinate, namely $s(\boldsymbol{a})^{2}+\|\boldsymbol{a}\|^{2}+1$. Thus $\boldsymbol{r}_{+}$is indeed a root (see the proof of Theorem 7). A similar argument shows that $\boldsymbol{r}_{-}$is a root as well.

Since each component of $\mathcal{S}_{n}$ has exactly one root, an immediate consequence of Proposition 11 is that

Theorem 12. For $n \geq 4$, both $\mathcal{S}_{n}^{+}$and $\mathcal{S}_{n}^{-}$have infinitely many components.
On the contrary, by examining the proof of Proposition 10, one readily checks that $(0,0,0)$ is the only root of $\mathcal{S}_{3}^{+}$. By Theorem 4, the map $\boldsymbol{a} \mapsto-(\boldsymbol{a}+\mathbf{1})$ where $\mathbf{1}=(1,1,1)$ is a graph isomorphism between $\mathcal{S}_{3}^{+}$and $\mathcal{S}_{3}^{-}$. Moreover, every element of $\mathcal{S}_{3}^{+}$is actually a fair game according to Proposition 5. Thus,

Theorem 13. $\mathcal{S}_{3}^{+}$and $\mathcal{S}_{3}^{-}$are the two components of $\mathcal{S}_{3}$. Moreover, $\mathcal{S}_{3}^{+}=\mathcal{F}_{3}$.
A straightforward computation shows that every vertex of $S_{3}$ with distinct coordinates has two distinct children (i.e., neighbors with a bigger norm). Moreover, each of its children also has distinct coordinates. Hence,

Theorem 14. The non-trivial 3-color fair games form an infinite full binary tree with $(0,1,3)$ as root.

## 5. The Set $\mathcal{C}_{n}$

Proposition 15. For $n \geq 4, \mathcal{C}_{n}$ is the set of non-negative integers.
Proof. For any $a \geq 0$, let $\boldsymbol{a}$ be the $(n-3)$-tuple with all coordinates equal $a$. Then the child $\left(4\left(s(\boldsymbol{a})^{2}+\|a\|^{2}\right)+3 s(\boldsymbol{a})+1, s(\boldsymbol{a})^{2}+\|\boldsymbol{a}\|^{2}, s(\boldsymbol{a})^{2}+\|\boldsymbol{a}\|^{2}, \boldsymbol{a}\right)$ of the positive root $\boldsymbol{r}_{+}$in Proposition 11 is a fair game with $a$ as a coordinate. Incidentally, this also shows that for $n \geq 4$, every natural number is a coordinate of some faithful $n$-color fair game.

This leaves us only $\mathcal{C}_{3}$ to study. It turns out that our analysis of $\mathcal{C}_{3}$ will yield another way of finding the 3 -color fair games (Theorems 17 and 18 ). First, note that $\mathcal{C}_{3}$ is the set of $c \geq 0$ such that the curve defined by

$$
\begin{equation*}
\left(x_{1}-x_{2}\right)^{2}-(2 c+1)\left(x_{1}+x_{2}\right)+c(c-1)=0 \tag{6}
\end{equation*}
$$

has a non-negative point. Arguing mod 2, one sees that any integral point on the parabola

$$
\begin{equation*}
u^{2}-(2 c+1) v+c(c-1)=0 \tag{7}
\end{equation*}
$$

Figure 2: Part of $\mathcal{F}_{3}$
must have coordinates with the same parity. Thus, the transformation $u=x_{1}-$ $x_{2}, v=x_{1}+x_{2}$ is a 1-to-1 correspondence between the integral points of these curves. Moreover, those $\left(x_{1}, x_{2}\right)$ 's with $x_{1}, x_{2} \geq 0$ correspond to the $(u, v)$ 's with $u \leq v$. However, the inequality is automatic:
Proposition 16. Solutions of Equation (7) are of the form

$$
(u, v)=\left(u, \quad \frac{u^{2}+c(c-1)}{2 c+1}\right)
$$

where $u^{2} \equiv-c(c-1) \bmod (2 c+1)$. In particular, (7) is solvable if and only if $-c(c-1)$ is a quadratic residue $\bmod (2 c+1)$. Moreover, $|u| \leq v$ for every integral solution $(u, v)$.

Proof. The first statement is clear by considering Equation (7) mod $(2 c+1)$. Note that for any $u$,

$$
-\frac{8 c+1}{4} \leq u^{2} \pm(2 c+1) u+c(c-1) .
$$

Since $c \geq 0$,

$$
\pm u-\frac{8 c+1}{8 c+4} \leq \frac{u^{2}+c(c-1)}{2 c+1}
$$

So in particular

$$
|u| \leq \frac{u^{2}+c(c-1)}{2 c+1}
$$

if both sides are integers. Therefore, $|u| \leq v$ for any integral solution of (7).
Solving for $x_{1}, x_{2}$ in terms of $u, v$ yields a parametrization of $\mathcal{F}_{3}$.
Theorem 17. The 3-color fair games are of the form

$$
\begin{equation*}
\left(\frac{u^{2}+(2 c+1) u+c(c-1)}{2(2 c+1)}, \quad \frac{u^{2}-(2 c+1) u+c(c-1)}{2(2 c+1)}, \quad c\right) \tag{8}
\end{equation*}
$$

where $c \in \mathcal{C}_{3}$ and $u^{2} \equiv-c(c-1) \bmod (2 c+1)$.
For $i=-1,0,1$, let $P_{i}$ be the set of primes that are congruent to $i \bmod 3$. Let $P_{i}^{\geq 0}$ be the set of natural numbers whose prime factors are all in $P_{i}$. With this notation, we have

Theorem 18. $\mathcal{C}_{3}=\left\{c: c \geq 0,2 c+1 \in P_{1}^{\geq 0} \cup 3 P_{1}^{\geq 0}\right\}$.
Proof. By Proposition 16 and the discussion preceding it, $\mathcal{C}_{3}$ is the set of all $c$ such that $-c(c-1)$ is a quadratic residue $\bmod 2 c+1$. Since $2 c+1$ is odd, $-c(c-1)$ and $-4 c(c-1)$ are either both squares or both non-squares $\bmod 2 c+1$. Note that $-4 c(c-1)$ is congruent to $-3 \bmod 2 c+1$. Therefore $c \in \mathcal{C}_{3}$ if and only if -3 is a square $\bmod 2 c+1$. This condition is equivalent to: for every prime $p,-3$ is a square $\bmod p^{v_{p}}$ where $v_{p}$ is the exponent of $p$ in $2 c+1$. That means $v_{3}=0$ or 1 and -3 is a quadratic residue $\bmod p$ for $p \neq 3$. The law of quadratic reciprocity then yields

$$
\left(\frac{-3}{p}\right)=\left(\frac{-1}{p}\right)\left(\frac{3}{p}\right)=(-1)^{\frac{1}{2}(p-1)}\left(\frac{3}{p}\right)=\left(\frac{p}{3}\right) .
$$

So the last condition is equivalent to $p \equiv 1 \bmod 3$. This completes the proof.
With the binary tree structure of $\mathcal{F}_{3}$ in mind, it is tempting to establish some relation between the equation for fair 3-color games and the Markoff equation (see [5] and [9] for more information on the Markoff equation), unfortunately we could not find any. However the naive analog of the Markoff conjecture (that the solution is uniquely determined by its largest coordinate) fails in our case, more precisely:

Theorem 19. For $c \in \mathcal{C}_{3}$ and $c>1$, the number of fair games with $c$ as the largest coordinate is $2^{m-1}$ where $m$ is the number of distinct prime factors of $2 c+1$ other than 3.

Proof. The coordinates of nontrivial 3-color fair games are distinct, so it follows from (8) that $c$ is the largest coordinate if and only if

$$
\begin{equation*}
c \geq \frac{u^{2}+(2 c+1)|u|+c(c-1)}{2(2 c+1)}+1 \tag{9}
\end{equation*}
$$

The above inequality implies $|u|$ cannot exceed the positive root of the quadratic polynomial $x^{2}+(2 c+1) x-(c-1)(3 c+2)$. From this it follows easily that $|u| \leq c$. On
the other hand, if $|u| \leq c$, then the right-hand side of (9) is an integer strictly less than $c+1$ and hence the inequality follows. Thus, proving the theorem boils down to counting the number of solutions to the congruence $u^{2} \equiv-c(c-1) \bmod (2 c+1)$, or equivalently $u^{2} \equiv-3 \bmod (2 c+1)$ in a complete set of representatives $(-c \leq u \leq$ $c)$. By Theorem 18, the prime factorization of $2 c+1$ is of the form $3^{v_{0}} p_{1}^{v_{1}} \cdots p_{m}^{v_{m}}$ where $v_{0}=0$ or 1 and $p_{j} \equiv 1 \bmod 3(1 \leq j \leq m)$. Note that $m \geq 1$ since $c>1$. The Chinese remainder theorem yields a 1 -to- 1 correspondence between solutions of $u^{2} \equiv-3 \bmod (2 c+1)$ and the solutions of the system $u^{2} \equiv-3 \bmod p_{j}^{v_{j}}$ $(1 \leq j \leq m)$ together with the congruence $u^{2} \equiv-3 \equiv 0 \bmod 3$ depending on whether $v=1$ or not. But the last congruence has only one solution and hence its presence will not affect the total number of solutions which is the product of the number of solutions of each congruence in the system. Since $p_{j} \neq 3(1 \leq j \leq m)$, the number of solutions for $u^{2} \equiv-3 \bmod p_{j}^{v_{j}}$ is the same as that for $u^{2} \equiv-3$ $\bmod p_{j}$ which is precisely two since $p_{j} \equiv 1 \bmod 3$. Therefore, we conclude that the system has exactly $2^{m}$ solutions. Finally, it is clear from (8) that $\pm u$ give rise to the same fair game except with the first two coordinates permuted. Thus, up to permutation of coordinates, there are $2^{m} / 2=2^{m-1}$ fair games with $c$ as the largest coordinate.

We conclude this section by computing the natural density of $\mathcal{C}_{3}$. The natural density of a set of natural numbers $A$ is defined to be $\lim _{k \rightarrow \infty}|A(k)| / k$ whenever the limit exists. Statement 2 of Corollary 2 states that $\mathcal{C}_{2}$ has density zero. The description of $\mathcal{C}_{3}$ in Theorem 18 allows us to show that the same phenomenon occurs in the case $n=3$ as well.

Theorem 20. The natural density of $\mathcal{C}_{3}$ is zero.
Proof. The map $a \mapsto 2 a+1$ is a bijection between $\mathcal{C}_{3}$ and $P_{1}^{\geq 0} \cup 3 P_{1}^{\geq 0}$. Therefore, the density of $\mathcal{C}_{3}$ is twice the density of $P_{1}^{\geq 0} \cup 3 P_{1}^{\geq 0}$ if the latter exists. Since $P_{1}^{\geq 0}$ and $3 P_{1}^{\geq 0}$ are disjoint and the density of $3 P_{1}^{\geq 0}$, if it exists, is one-third that of $P_{1}^{\geq 0}$, it suffices to show that $P_{1}^{\geq 0}$ has density 0. Applying Proposition 9.64 and Lemma 11.8 in [3] to the set $P_{1}^{\geq 0}=P_{1}^{\geq 0} P_{0}^{0} P_{-1}^{0}$, we see that it is enough to show that the series $\sum_{p \in P_{-1}} 1 / p$ diverges. But this assertion is an immediate consequence of Dirichlet's theorem of primes in arithmetic progressions [12, Chapter VI Theorem 2]) which, in particular, asserts that

$$
\lim _{s \rightarrow 1^{+}} \frac{\sum_{p \in P_{-1}} 1 / p^{s}}{\log (1 /(s-1))}=\frac{1}{\phi(3)}=\frac{1}{2}
$$

## 6. Asymptotic Behavior

Compared to the binary case, determining the asymptotic behavior of $\left|\mathcal{F}_{n}(k)\right|$ $(n \geq 3)$ seems to be a much harder problem. In fact, we will only show that $\left|\mathcal{F}_{3}(k)\right|$ is $\Theta(k)$. Our strategy is to relate the equation for 3-color fair games to the Lorentzian form $L_{3}(w)=w_{1}^{2}+w_{2}^{2}-w_{3}^{2}$, and then apply the results from [11] (for more information on distribution of integral points on affine homogenous varieties, see [6] and [2]). Let $W$ be the set of integral solutions of $L_{3}(w)=-3$.

Lemma 21. For any $\left(w_{1}, w_{2}, w_{3}\right) \in \mathbf{W}$, we have

1. $\left|w_{3}\right|>\left|w_{1}\right|,\left|w_{2}\right|$.
2. Exactly one of the $w_{i}$ is odd; moreover, it must be either $w_{1}$ or $w_{2}$.
3. If $w_{2}$ is the odd coordinate then $w_{1}+w_{3} \equiv w_{1}-w_{3} \equiv 2 \bmod 4$.
4. $w_{1} \neq w_{2}$.

Proof. The first statement is immediate. The second statement is clear by arguing $\bmod 8$. Since $w_{2}$ is odd, $w_{1}^{2}-w_{3}^{2} \equiv 0 \bmod 4$. Since $w_{3}$ is even, $w_{1}+w_{3} \equiv w_{1}-w_{3}$ $\bmod 4$. They must both be congruent to $2 \bmod 4$; otherwise $w_{1}^{2}-w_{3}^{2} \equiv 0 \bmod 8$ making -3 a square $\bmod 8$, a contradiction. This establishes the third statement. The last statement is true since $2 w_{1}^{2}-w_{3}^{2}=-3$ is not solvable mod 3 .

Let $\approx$ be the equivalence relation on $\mathbf{W}$ identifying the elements $\left(w_{1}, w_{2}, w_{3}\right)$ and $\left(w_{2}, w_{1}, w_{3}\right)$. It follows from part 4 of Lemma 21 that the canonical map from W to $\mathrm{W} / \approx$ is 2 -to- 1 . If we identify the equivalence classes with those elements of W with an odd second coordinate, then we obtain

Proposition 22. The map given by

$$
\begin{equation*}
w_{1}=2\left(x_{2}-x_{3}\right), \quad w_{2}=2\left(x_{1}-x_{2}-x_{3}\right)-1, \quad w_{3}=2\left(x_{2}+x_{3}+1\right) \tag{10}
\end{equation*}
$$

is a 1-to-1 correspondence between $\mathcal{S}_{3}$ and $\mathrm{W} / \approx$. Moreover, if the coordinates of the elements of $\mathcal{S}_{3}$ are listed in ascending order, then the elements of $\mathcal{F}_{3}$ correspond to those elements of $\mathrm{W} / \approx$ with $w_{1}, w_{2} \leq 0$ and $w_{3} \geq 0$.

Proof. The rational inverse of the map in (10) is given by

$$
\begin{equation*}
x_{1}=\frac{w_{2}+w_{3}-1}{2}, \quad x_{2}=\frac{w_{1}+w_{3}-2}{4}, \quad x_{3}=\frac{w_{3}-w_{1}-2}{4} . \tag{11}
\end{equation*}
$$

By Lemma 21, parts 2 and 3, it actually preserves integral points. This establishes that the map in (10) is a 1-to- 1 correspondence between $\mathcal{S}_{3}$ and $\mathrm{W} / \approx$. Moreover, the images of elements of $\mathcal{F}_{3}$ (as ascending triples) under (10) clearly satisfy $w_{1}, w_{2} \leq 0$ and $w_{3} \geq 0$. Conversely, by part 1 of Lemma $21,\left|w_{3}\right| \geq\left|w_{2}\right|+1$ and $\left|w_{3}\right| \geq\left|w_{1}\right|+2$ since both $w_{1}$ and $w_{3}$ are odd (Lemma 21, part 2). Therefore, if $\left(w_{1}, w_{2}, w_{3}\right) \in \mathrm{W}$ with $w_{1}, w_{2} \leq 0$ and $w_{3} \geq 0$ then the corresponding $\left(x_{1}, x_{2}, x_{3}\right)$ is in $\mathcal{F}_{3}$.

Theorem 23. There exist positive constants $c_{1}, c_{2}$ such that $c_{1} k \leq\left|\mathcal{S}_{3}(k)\right| \leq c_{2} k$ for $k$ sufficiently large, i.e., $\left|\mathcal{S}_{3}(k)\right|=\Theta(k)$. Similarly, $\left|\mathcal{F}_{3}(k)\right|=\Theta(k)$.

Proof. The idea is simple: the sphere of radius $k$ centered at the origin maps to an ellipsoid (centered at $(0,-1,2)$ ) under (10). For $k$ sufficiently large, it is enveloped between spheres centered at the origin. Clearly, the radii of these spheres can be chosen as linear functions of the length of the axes of the ellipsoid which are in turn linear in $k$ since the transformation given in (10) is affine. So by Proposition 22, the proof is complete once we show that $|\mathrm{W}(k)|$ is asymptotic to a linear function in $k$. And this last statement follows from Formula (3) in [11] which asserts that $\left|\mathrm{W}_{3}(k)\right| \sim(4 \sqrt{6} / 3) k$.

## Remarks

(i) Since the maps and the equations are all explicit, one can provide the constants $c_{1}$ and $c_{2}$ in Theorem 23 explicitly. However, we will leave the computation for the interested readers.
(ii) In a sense, one gets a cleaner result without extra efforts if one is satisfied by counting the number of solutions inside the ellipsoids that are the images of spheres under the map given in (11). To be more precise, let $\mathcal{S}_{3}^{\prime}(k)$ and $\mathcal{F}_{3}^{\prime}(k)$ be the set elements of $\mathcal{S}_{3}$ and $\mathcal{F}_{3}$ inside the image of the sphere of radius $k$ centered at the origin under the map given in (11). Then again using Formula (3), Table (1) in [11] and Proposition 22, one gets

$$
\left|\mathcal{S}_{3}^{\prime}(k)\right|=\frac{1}{2}|\mathrm{~W}(k)| \sim \frac{2 \sqrt{6}}{3} k, \quad\left|\mathcal{F}_{3}^{\prime}(k)\right| \sim \frac{6}{8} \frac{1}{2}|\mathrm{~W}(k)|=\frac{\sqrt{6}}{2} k
$$

(iii) Here is how we arrive to the map in (10): There is a general method of solving quadratic Diophantine equations given by Grunewald and Segal in $[7]$ and $[8]^{4}$. The first step transforms the fair game equation into the equivalent system

$$
\begin{equation*}
Q_{n}(\boldsymbol{z})=-n(n-2), \quad z_{i} \equiv 1 \quad \bmod 2(n-2) . \quad(1 \leq i \leq n) \tag{12}
\end{equation*}
$$

where $Q_{n}$ is the quadratic form in $n$-variables with diagonal entries 1 and offdiagonal entries -1 . When $n=3$, one checks readily that congruences in (12) are implied by $Q_{3}(\boldsymbol{z})=-3$. And the Lorentzian form $L_{3}(\boldsymbol{w})$ is obtained by diagonalizing $Q_{3}$. Taking the composition of these transformations yields the map in (10).
(iv) In the ternary case, the description of the solution set given by Grunewald and Segal's method relates quite beautifully to ours. We encourage the reader to pursuit their original papers (see [4] for the necessary backgrounds). Just to

[^3]give a little enticement, let us remark that $\mathcal{S}_{3}$ will correspond to a single orbit under the integral orthogonal group of a suitable quadratic form. While $\mathcal{S}_{3}^{+}$ (i.e., $\mathcal{F}_{3}$ ) and $\mathcal{S}_{3}^{-}$will correspond to two orbits of a subgroup of the orthogonal group.
(v) Using the same idea to study $\left|\mathcal{F}_{n}(k)\right|$ for $n \geq 4$ becomes more problematic. First, it is not clear to us how to take into account the congruences in (12). Moreover, even though $Q_{n}$ and the Lorentzian form in $n$-variables have the same signature, namely $n-2$, the transformation taking one to the other in general does not preserve integral points.

## 7. Odds and Ends

The last section is dedicated to various results that do not quite fit in previous sections.

Proposition 24. The sum of coordinates of any element of $S_{n}$ is congruent to either 0 or $1 \bmod 4$.

Proof. Equation (1) is simply $s^{2}-s=4 p$.
Proposition 25. Every vertex in the connected component of $\mathbf{0}$ in $\mathcal{S}_{n}$ is congruent $\bmod 3$ to either $\mathbf{0}$ or $\boldsymbol{e}_{j}:=(0, \ldots, 1, \ldots, 0)$ for some $1 \leq j \leq n$.

Proof. The proposition is clearly true for $\mathbf{0}$. Now suppose it is true for every vertex of distance $m$ from $\mathbf{0}$. Let $\boldsymbol{a}^{\prime}=\left(a_{1}, \ldots, a_{i}^{\prime}, \ldots, a_{n}\right)$ be a vertex of distance $m+1$ from $\mathbf{0}$ and adjacent to $\boldsymbol{a}=\left(a_{1}, \ldots, a_{i}, \ldots, a_{n}\right)$ which is of distance $m$ from $\mathbf{0}$. By the induction hypothesis, $\boldsymbol{a}$ is congruent to either $\mathbf{0}$ or $\boldsymbol{e}_{j} \bmod 3$ for some $1 \leq j \leq n$. Since $a_{i}+a_{i}^{\prime}=1+2 s_{i}(\boldsymbol{a}) \equiv 1-s_{i}(\boldsymbol{a}) \bmod 3$, we have the following 3 cases

1. $\boldsymbol{a}^{\prime} \equiv \boldsymbol{e}_{i} \bmod 3$ if $\boldsymbol{a} \equiv \mathbf{0} \bmod 3$,
2. $\boldsymbol{a}^{\prime} \equiv \boldsymbol{e}_{j} \bmod 3$ if $\boldsymbol{a} \equiv \boldsymbol{e}_{j} \bmod 3$ and $i \neq j$, or
3. $\boldsymbol{a}^{\prime} \equiv \mathbf{0} \bmod 3$ if $\boldsymbol{a} \equiv \boldsymbol{e}_{j} \bmod 3$ and $i=j$.

This establishes the proposition by induction.
Recall that for $n \geq 4$ any natural number, in particular 2, can be a coordinate of an $n$-color fair game (Proposition 15). Thus, Proposition 25 gives another proof of the fact that $\mathcal{F}_{n}$ is disconnected for $n \geq 4$.

The nontrivial 3-color fair games form a full binary tree with the nontrivial 2color fair games embedded as a branch. It is easy to see that among the nodes of distance $k$ from the root $(0,1,3)$, the one with the smallest norm is $\left(0,\binom{k+2}{2},\binom{k+3}{2}\right)$
and the one with the largest norm is $\left(m_{k}, m_{k+1}, m_{k+2}\right)$ where $\left(m_{i}\right)$ is the sequence defined recursively by $\left(m_{0}, m_{1}, m_{2}\right)=(0,1,3)$ and $m_{i+3}=2\left(m_{i+1}+m_{i+2}\right)+1-m_{i}$ for $i \geq 0$. It turns out that the $m_{i}$ 's have an intimate relationship with the Fibonacci numbers.

Proposition 26. Let $f_{i}$ be the $i$-th Fibonacci number. Then for any $k \geq 0$

$$
m_{k}= \begin{cases}f_{k}^{2} & \text { if } k \text { is odd } \\ f_{k}^{2}-1 & \text { if } k \text { is even }\end{cases}
$$

Proof. The Fibonacci numbers are defined inductively by $f_{0}=f_{1}=1$, and $f_{i+2}=$ $f_{i}+f_{i+1}(i \geq 0)$. Note that

$$
\begin{aligned}
2 f_{i+1} f_{i+2} & =f_{i+1}\left(f_{i+2}+f_{i}+f_{i+1}\right)=f_{i+1}\left(f_{i+2}+f_{i}\right)+f_{i+1}^{2} \\
& =\left(f_{i+2}-f_{i}\right)\left(f_{i+2}+f_{i}\right)+f_{i+1}^{2} \\
& =f_{i+2}^{2}+f_{i+1}^{2}-f_{i}^{2}
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
f_{i+3}^{2} & =\left(f_{i+1}+f_{i+2}\right)^{2}=f_{i+1}^{2}+2 f_{i+1} f_{i+2}+f_{i+2}^{2} \\
& =2 f_{i+1}^{2}+2 f_{i+2}^{2}-f_{i}^{2}
\end{aligned}
$$

The proposition now follows from an easy induction. The base cases are immediate. Suppose $k \geq 3$ and the proposition is true for all $0 \leq i<k$. When $k$ is odd, we have

$$
\begin{aligned}
m_{k} & =2\left(m_{k-2}+m_{k-1}\right)+1-m_{k-3} \\
& =2\left(f_{k-2}^{2}+f_{k-1}^{2}-1\right)+1-\left(f_{k-3}^{2}-1\right) \\
& =2 f_{k-2}^{2}+2 f_{k-1}^{2}-f_{k-3}^{2} \\
& =f_{k}^{2}
\end{aligned}
$$

A similar computation shows that $m_{k}=f_{k}^{2}-1$ when $k$ is even.
We end the article with another curious "by-product" of our results.
Proposition 27. For $m \geq 0$,

1. $m^{2}+m+1 \in P_{1}^{\geq 0} \cup 3 P_{1}^{\geq 0}$.
2. $2 f_{m}^{2}-(-1)^{m} \in P_{1}^{\geq 0} \cup 3 P_{1}^{\geq 0}$.

Proof. Triangular numbers $m(m+1) / 2(m \geq 0)$ appear as coordinates of the 2-color (Theorem 1) and hence 3-color fair games. By Theorem 18, we have $m^{2}+m+1=$ $2(m(m+1) / 2)+1 \in P_{1}^{\geq 0} \cup 3 P_{1}^{\geq 0}$. Similarly, Statement 2 follows from Proposition 26 and Theorem 18.
