

**CONNECTED SUBTRACTION GAMES ON SUBDIVIDED STARS¹****Antoine Dailly²***Univ. Grenoble Alpes, CNRS, Grenoble INP, Grenoble, France**Univ Lyon, Université Lyon 1, Lyon, France***Julien Moncel***LAAS-CNRS, Université de Toulouse, CNRS, Université Toulouse 1, Toulouse, France**Fédération de Recherche Maths à Modeler, Institut Fourier, Saint-Martin d'Hères, France***Aline Parreau***Univ Lyon, Université Lyon 1, Lyon, France**Received: 7/25/18, Revised: 5/13/19, Accepted: 7/18/19, Published: 7/31/19***Abstract**

The present paper deals with connected subtraction games on graphs, which are generalizations of take-away games. In a connected subtraction game, two players alternate removing a connected subgraph from a given connected game-graph, provided the resulting graph is connected, and provided the number of vertices of the removed subgraph belongs to a prescribed set of integers. We derive general periodicity results on such games, as well as specific results when played on subdivided stars.

1. Connected Subtraction Games on Graphs**1.1. General Description of the Game**

In this paper, we study *connected subtraction games* on graphs, which are impartial combinatorial games where a player can remove a connected subgraph from a given connected game-graph, provided each move leads to a new game-graph which remains connected, and provided the number of vertices that have been removed is legal, with respect to a given list of integers that characterizes the game. Such a game will be called a *CS* game.

More precisely, let L be a nonempty set of positive integers and G a connected graph. The game $CSG(L)$ on G is a 2-player game where, starting from G , a player can remove a connected subgraph H from the current graph whenever the number of vertices of H belongs to L and the remaining graph is still connected. The first player unable to play loses the game. See Figure 1 for an example of a game $CSG(\{1, 2, 4\})$.

Figure 1: An example of a game of $CSG(\{1, 2, 4\})$. The first player starts by taking the connected subgraph induced by vertices $\{1, 2, 3, 4\}$. Then the second player answers by taking vertex 5. Finally, the first player wins by taking the last edge $\{6, 7\}$.

In some sense, this game is a natural generalization of popular take-away games, that are usually played with heaps of counters, in which a player can remove a number of counters belonging to a given set L . In the theory of combinatorial games, this is called a (simple) subtraction game (see, for instance, Chapter 4 in the first volume of [4]). From a graph theory point of view, such subtraction games can be seen as games $CSG(L)$ played on paths.

Connected subtraction games on graphs have been addressed in [3], where the game $CSG(\{1, 2\})$ is solved for subdivided stars and bistars. In the present paper we extend these results, by providing, on the one hand, insights for such games in general (connected) graphs, and, on the other hand, specific results for $CSG(\{1, 2, 3\})$ and $CSG(\{1, 2, 4\})$ in subdivided stars.

1.2. Notation for Combinatorial Games, Outcomes and Grundy Values

Throughout this section, we recall basics of combinatorial games that we will need along the paper. For more about combinatorial games, the reader can refer to [2, 4, 11]. In the classical settings of combinatorial game theory, two players play in turn without being able to pass. The game is finite (the number of positions is finite and we cannot cycle through some positions), there are no random events, and the information is perfect (each player knows what is the situation and what are the possible moves). In addition, both players are identical in the sense that they have the same available moves (such a game is called *impartial*). The first player having no available move loses the game (and the other player wins). Note that such games admit no draws.

In this setting, a given game is either a winning position or a losing position for the first player. We can recursively define losing and winning positions as follows. A given game is a losing position if it is either a game in which there are no available moves, or if it is a game in which each possible move leads to a winning position. A given game is a winning position if there exists a move leading to a losing position. A losing position is denoted as a \mathcal{P} -position, whereas a winning one is denoted as an \mathcal{N} -position.

We can also recursively define the *Grundy value* of a given game G , denoted $\mathcal{G}(G)$, as 0 if there are no possible moves, and as $\text{mex}\{\mathcal{G}(G_1), \dots, \mathcal{G}(G_k)\}$ otherwise, where G_1, \dots, G_k denote all the options of G that are all the games we may obtain after playing one move on G . Recall that the *mex* of a finite sequence of nonnegative integers is defined as the smallest nonnegative integer not belonging to the sequence. Note that it follows from the definition that G is a losing position if and only if $\mathcal{G}(G) = 0$. Winning positions correspond to games G for which we have $\mathcal{G}(G) > 0$. Indeed, a game has Grundy value $g > 0$ if and only if no move leads to a game having Grundy value g , and for every g' with $0 \leq g' < g$, there exists a move leading to a game having Grundy value g' . Therefore, the Grundy value is a refinement of the notion of outcome, i.e., winning or losing positions. We generally consider that a game is completely solved if we know its Grundy value.

Grundy values are particularly useful when dealing with games that can be decomposed as sums of games. The sum of two games G_1 and G_2 , denoted $G_1 + G_2$, is the new game where a player can either play on G_1 (with any legal move on that game) or play on G_2 (with any legal move on that game).

It turns out that the Grundy value of a sum of games can be easily computed from the Grundy values of the games. It is easy to see that, for instance, $\mathcal{G}(G + G) = 0$ for any game G . Indeed, we can show recursively that any move the first player makes on $G + G$ can be mimicked by the second player so as to leave a game $G' + G'$. Since there are no moves in $\emptyset + \emptyset$, this shows that $\mathcal{G}(G + G) = 0$. More generally, the so-called Sprague-Grundy Theorem [12] states that the binary value of $\mathcal{G}(G_1 + G_2)$ can be computed as $\mathcal{G}(G_1) \oplus \mathcal{G}(G_2)$, where \oplus denotes the bitwise XOR of the binary values of both games. For instance, the Grundy value of $G_1 + G_2$ is 3 if $\mathcal{G}(G_1) = 5$ and $\mathcal{G}(G_2) = 6$, since $5_2 = 101$, $6_2 = 110$, and $101 \oplus 110 = 011$, that is to say 3. A consequence of the Sprague-Grundy Theorem is that two games G_1 and G_2 have the same Grundy value if and only if $G_1 + G_2$ is a losing position. In this case we say that G_1 and G_2 are *equivalent*, denoted by $G_1 \equiv G_2$. We will often use this property to compute the Grundy value of a game.

In this paper, we will denote by $\mathcal{G}_L(G)$ the Grundy value of the game $CSG(L)$ played on a graph G . If the context is clear, we will simply write $\mathcal{G}(G)$. Furthermore, since the removed vertices have to be connected, we will only consider the game played on connected graphs. Indeed, if a graph G is composed of connected components G_1, \dots, G_k , then the Sprague-Grundy Theorem implies that

$$\mathcal{G}(G) = \mathcal{G}(G_1) \oplus \dots \oplus \mathcal{G}(G_k).$$

1.3. Literature Review

It is well-known (see for instance [4]) that any simple subtraction game with a finite set L is ultimately periodic, in the sense that their *Grundy sequence*, which is the sequence of their Grundy values for heaps of increasing size, is ultimately periodic: there exists a period $T > 0$ and an integer k_0 such that, for any $k \geq k_0$, we have $\mathcal{G}(G_{k+T}) = \mathcal{G}(G_k)$, where G_k denotes the game played with a heap of k counters. Such ultimately periodic sequences of integers can be described using the $\overline{x_1, \dots, x_k}$ notation, where $\overline{x_1, \dots, x_k}$ denotes the infinite sequence $x_1, \dots, x_k, x_1, \dots, x_k, \dots$. For instance, it is well-known and easy to check that $(\mathcal{G}(G_k))_{k \in \mathbb{N}} = \overline{0123}$ for the subtraction game with $L = \{1, 2, 3\}$, meaning that, for instance, $\mathcal{G}(G_2) = 2$ and $\mathcal{G}(G_4) = 0$ (the sequence starts with the value corresponding to $k = 0$). Note that, in general, the sequence is ultimately periodic, meaning we may have a preperiod [4, Chapter 4]. For instance, for the subtraction game with $L = \{2, 4, 7\}$, the Grundy sequence has preperiod 8 and period 3, since we have:

$$(\mathcal{G}(G_k))_{k \in \mathbb{N}} = 00112203\overline{102}.$$

Subtraction games are take-away games³, which is the family of games that includes more or less all combinatorial games played on heaps of counters where players remove counters with some specific rules. The ultimate periodicity of such games has been conjectured by Guy [8] and is a key problem in Combinatorial Game Theory. See [4] for more details on take-away games and their periodicity.

There exist several generalizations of take-away games in graphs. In [6, 7], the edges of the graphs are labeled with an integer and a token is moved along the edges. In Node-Kayles [10], a move consists in removing a vertex and all its neighbours from the graph. If instead of removing vertices players remove edges, we obtain Arc-Kayles [10]. In the game Grim defined and studied in [1], a move consists in removing a vertex, deleting its adjacent edges, and deleting the resulting isolated vertices. Finally, a general definition of octal games on graphs and specifically of subtraction games has been recently given in [3].

A natural question that arises in these generalizations in graphs is whether the (ultimate) periodicity of the Grundy sequences that appear in classical take-away games (that can be considered as a particular case of connected subtraction games played on paths) is still valid for more complicated graphs. This question has been studied for Node-Kayles [5] and Arc-Kayles [9] in the particular class of subdivided stars (which is the simplest generalization of paths). For both games, the authors are able to prove that the sequence is still (ultimately) periodic for specific subdivided stars with three rays. Huggan and Stevens [9] have conjectured that this is true

³Also called Nim-like games, or octal games.

for Arc-Kayles for all subdivided stars with three rays, one of which is of size 1, whereas Fleischer and Trippen [5] proved that this is not true for Node-Kayles. As for the game $CSG(\{1, 2\})$ on graphs, it is proved in [3] that it is periodic in all subdivided stars and bistars. More precisely, if we denote by $S_{\ell_1, \dots, \ell_k}$ the subdivided star obtained by appending to a single vertex k finite paths of length ℓ_1, \dots, ℓ_k , it is shown in [3] that

$$\mathcal{G}_{1,2}(S_{\ell_1, \dots, \ell_k}) = \mathcal{G}_{1,2}(S_{\ell_1 \bmod 3, \dots, \ell_k \bmod 3})$$

for all ℓ_1, \dots, ℓ_k . In other words, adding three vertices to any path of a subdivided star does not change its Grundy value. Note that this value 3 is also equal to the period of the subtraction game with $L = \{1, 2\}$. Similar results for subdivided bistars are also derived in [3], where a bistar is a graph obtained by connecting with a path the centers of two subdivided stars.

1.4. Outline of the Paper

In this paper we are interested in deriving general results on CSG games, with a particular emphasis on the correlation of the structure of the graphs with the structure of the Grundy values.

Most of our results are about the behavior of the Grundy value when one appends a path of a given size to a vertex of a graph. Let G be a graph, u one of its vertices and k a positive integer. We denote by $G \overset{\bullet}{u} \rightarrow P_k$ the graph obtained from G by appending a path P_k of k vertices to u (u not being a part of this path). We extend this notation to the case where G is the null graph, by setting in this case $G \overset{\bullet}{u} \rightarrow P_k = P_k$. We are interested in the periodicity of the function

$$f_{L,G,u} : \mathbb{N} \rightarrow \mathbb{N} \\ k \mapsto \mathcal{G}_L(G \overset{\bullet}{u} \rightarrow P_k).$$

for various sets L .

In Section 2, we give results for any subtraction game on a finite set. In particular, we extend the result of ultimate periodicity on paths to any graph. In other words, the function $f_{L,G,u}$ is ultimately periodic for any finite set L , graph G and vertex u of G . In the rest of the paper, we aim to prove pure periodicity, that is, periodicity without preperiod. In Section 3, we derive general results for the game $CSG(\{1, 2, \dots, N\})$, that is, the game where any connected subgraph of order up to N can be removed. These results concern general graphs and subdivided stars to which paths are appended. They allow us to solve the particular case of the game $CSG(\{1, 2, 3\})$ in subdivided stars. In Section 4, we derive periodicity results for $CSG(\{1, 2, 4\})$ in subdivided stars.

2. General Results on Finite Subtraction Games

As said in the introduction, simple subtraction games with a finite set L have ultimately periodic Grundy sequences (see Chapter 4 of [11] for a proof). Using our terminology, this means that if L is finite, the function $f_{L,G,u}$ is ultimately periodic when G is a path and u is an endpoint of G . The main argument to prove this result is that when a path is long enough, all the moves in L are possible and the number of moves is finite. Thus the Grundy value of a long path is the mex over a finite set. This set can only have a finite number of values, which proves the periodicity. We extend this argument to any graph and any vertex.

Theorem 1. *Let L be a finite set of positive integers, G a graph and u a vertex of G . Then the function $f_{G,L,u}$ is ultimately periodic.*

Proof. We proceed by induction on $|G|$, where $|G|$ denotes the number of vertices of G . The case $|G| = 1$ corresponds to the case of paths, and thus to simple subtraction games.

Let G be a graph with at least two vertices and u be a vertex of G . Let G' be a proper connected subgraph of G containing u . Assume that the function $f_{G',L,u}$ is ultimately periodic with period $T(G')$ and preperiod $k(G')$. Let k_0 and T_0 be the preperiod and the ultimate period of the Grundy sequence of the subtraction game with set L . Let T be the lcm of T_0 and all the values $T(G')$, with G' any proper connected subgraph of G containing u , and let k_{max} be the maximum of the preperiods among the preperiods $k(G')$ and k_0 .

If $k \geq \max L$, then the set of available moves is fixed, and there are three kinds of moves from the position $G \bullet_u \bullet P_k$:

1. playing to $G \bullet_u \bullet P_{k-i}$ with $i \geq 1$ (at most $|L|$ moves);
2. playing to $G' \bullet_u \bullet P_k$, with G' a proper connected subgraph of G containing u (at most $2^{|G|-1}$ moves);
3. playing to P_{k-i} with $i \geq 1$ (at most $|L|$ moves).

Thus, the total number of moves is bounded by a constant M only depending on L and G (but not depending on k). Thus the Grundy value of $G \bullet_u \bullet P_k$, $f_{G,L,u}(k)$, is bounded by M .

Let $k \in \mathbb{N}$ and $A(k) \in \{0, \dots, M\}^{|L|}$ be the $|L|$ consecutive values of the Grundy values of $G \bullet_u \bullet P_i$ from $i = k + 1$ to $i = k + |L|$:

$$A(k) = (f_{G,L,u}(k + 1), f_{G,L,u}(k + 2), \dots, f_{G,L,u}(k + |L|)).$$

The vector $A(k)$ is an $|L|$ -tuple with values in $\{0, \dots, M\}$. Since there are a finite number of such $|L|$ -uplets, and since $k \in \mathbb{N}$, then there exist k_1 and k_2 such

that $A(k_1) = A(k_2)$. Moreover, we can assume that $k_{max} + |L| \leq k_1 \leq k_2$ and that $k_1 \equiv k_2 \equiv 0 \pmod T$. Indeed, there are also infinitely many values of k with $k \geq k_{max} + |T|$ and $k \equiv 0 \pmod T$, hence at least two of them must be equal.

Let $T_f = k_2 - k_1$. We prove by induction that for any $k > k_1$, $f_{G,L,u}(k + T_f) = f_{G,L,u}(k)$ which will conclude the proof. By definition of k_1 and k_2 , the result is true for $k_1 < k \leq k_1 + |L|$. Let $k > k_1 + |L|$ and assume that the result is true for the $|L|$ values preceding k . We prove that this is still true for k . Remember that, since $k \geq \max L$, the set of available moves is fixed, and the value $f_{G,L,u}(k + T_f)$ is the mex of the following values:

1. $f_{G,L,u}(k + T_f - i)$ with $1 \leq i \leq |L|$;
2. $f_{G',L,u}(k + T_f)$, with G' a proper connected subgraph of G containing u ;
3. $\mathcal{G}(P_{k+T_f-i})$ with $1 \leq i \leq |L|$.

By induction hypothesis, $f_{G,L,u}(k + T_f - i) = f_{G,L,u}(k - i)$. Furthermore, T_f is a multiple of T and $k \geq k_{max}$, and thus $f_{G',L,u}(k + T_f) = f_{G',L,u}(k)$ and $\mathcal{G}(P_{k+T_f-i}) = \mathcal{G}(P_{k-i})$. Finally, since the sets of available moves from $G \overset{u}{\bullet} \bullet P_{k+T_f}$ and from $G \overset{u}{\bullet} \bullet P_k$ are identical, $f_{G,L,u}(k + T_f)$ and $f_{G,L,u}(k)$ are actually both a mex computed on the same set of values, and thus are equal. \square

The preperiod and the period obtained in Theorem 1 can be arbitrarily large, even compared to the period of the Grundy sequence of the subtraction game played on a path. However, in all the particular cases we have considered, the period is the same as for the path. We wonder if this is true for all subtraction games. Concerning the preperiod, for some simple subtraction games there is no preperiod and the Grundy sequence is purely periodic. This is the case, for example, when the set L contains all the integers from 1 to N . In the rest of the paper, we aim at proving "pure periodicity" theorems.

Some of our results use the following lemma.

Lemma 2. *Let us consider the game $CSG(L)$, with L a finite set, played on some family of graphs \mathcal{F} which has the property that the Grundy value of the game when played on any graph G of \mathcal{F} only depends on the cardinality of G modulo a given period. More precisely, let us assume that there exists $T > 0$ and integers $\alpha_0, \dots, \alpha_{T-1}$ satisfying $\{\alpha_0, \dots, \alpha_{T-1}\} = \{0, \dots, T - 1\}$ such that $\mathcal{G}(G) = \alpha_{\|G\|}$ for any $G \in \mathcal{F}$, with $\|G\|$ defined as $|G| \pmod T$. Let \mathcal{F}' be a family of graphs such that:*

- any legal move played on a graph $G \in \mathcal{F}'$ leads to a graph in \mathcal{F}
- the set of legal moves played on a graph $G \in \mathcal{F}'$ satisfies

$$\{k \pmod T \mid \text{there exists a legal move removing } k \text{ vertices to } G\} = \{1, \dots, T - 1\}. \tag{1}$$

Then, for any graph $G \in \mathcal{F}'$, we also have $\mathcal{G}(G) = \alpha_{\|G\|}$.

Proof. Let us denote by H^k the set of graphs of \mathcal{F} that are obtained after playing any legal move consisting in removing k vertices from a graph G in \mathcal{F}' . By the definition of \mathcal{F} , we have $\mathcal{G}(H) = \alpha_{\|H\|}$ for any $H \in H^k$. Since $|H| = |G| - k$, we have $\mathcal{G}(H) = \alpha_{\|G\| - k \bmod T}$ for any such graph. Now, since (1) is assumed to be true, we have

$$\begin{aligned} \mathcal{G}(G) &= \text{mex}\{\mathcal{G}(H) \mid H \text{ is obtained by a legal move from } G\} \\ &= \text{mex}\{\alpha_{\|G\| - k \bmod T} \mid \text{there exists a legal move removing } k \text{ vertices from } G\} \\ &= \text{mex}\{\alpha_{\|G\| - 1 \bmod T}, \alpha_{\|G\| - 2 \bmod T}, \dots, \alpha_{\|G\| - T + 1 \bmod T}\}. \end{aligned}$$

Since we assumed, moreover, that $\{\alpha_0, \dots, \alpha_{T-1}\} = \{0, \dots, T - 1\}$, we conclude that $\mathcal{G}(G) = \alpha_{\|G\|}$, which is the desired result. \square

By inductively using this lemma, we will derive periodicity results for some specific families of subdivided stars, which will be useful for the study of $CSG(\{1, 3\})$ and $CSG(\{1, 2, 4\})$ in subdivided stars.

In the sequel, this lemma will mainly be used in the special case where $\alpha_i = i$ for each i . In other words, \mathcal{F} is such that $\mathcal{G}(G) = |G| \bmod T$ for all $G \in \mathcal{F}$.

We end this section with a simple observation.

Observation 3. *For any graph G and any set L of integers, we have $\mathcal{G}_L(G) \leq |G|$.*

Proof. We prove the result by induction on G . This is true if G is empty since the Grundy value of the empty graph is 0. Let G' be a graph obtained after a legal move on G . The graph G' has strictly less vertices than G . Thus by induction, $\mathcal{G}_L(G') \leq |G'| < |G|$. Finally, since $\mathcal{G}_L(G) = \text{mex}\{\mathcal{G}_L(G') \mid G' \text{ option of } G\}$, we have $\mathcal{G}_L(G) \leq |G|$. \square

3. Connected Subtraction Games Where We Can Remove Up to N Vertices

For a general finite set L , the period and the preperiod of the Grundy sequence of Theorem 1 can be very large, as is already the case for paths. Since the subtraction game on paths for the set $L = \{1, \dots, N\} = I_N$ is very simple, we focus on this game in this section and give periodicity results with small period, and without — or with a very short — preperiod. We first give general results, valid for any N and any graph G . Then we focus on two families of subdivided stars and prove results that are still valid for any N . Finally, we apply these results to $N = 3$ and completely solve the corresponding game for subdivided stars. Note that the case $N = 2$ is solved in [3].

3.1. Results on General Graphs

We first recall the Grundy sequence of the game $CSG(I_N)$ on paths,

Lemma 4 (Folklore). *Let N and k be two nonnegative integers. We have $\mathcal{G}_{I_N}(P_k) = k \bmod (N + 1)$, i.e., $(\mathcal{G}_{I_N}(P_k))_{k \in \mathbb{N}} = \overline{012\dots N}$, where P_k denotes the path on k vertices.*

We now give some results on $\mathcal{G}_{I_N}(G)$ that depend only on the number of vertices of G , when this last one is small enough. We will generalize this result when considering some specific stars (see Lemma 13).

Lemma 5. *For any graph G and any integer $N \geq 1$, we have $\mathcal{G}_{I_N}(G) = |G|$ if $|G| \in \{0, 1\}$, $\mathcal{G}_{I_N}(G) \geq 2$ if $|G| \in \{2, \dots, N\}$, $\mathcal{G}_{I_N}(G) = 0$ if $|G| = N + 1$, and $\mathcal{G}_{I_N}(G) = 1$ if $|G| = N + 2$.*

Proof. There is no possible move in the empty graph and, since $1 \in I_N$, the only possible move from a single vertex is to take it to play to the empty graph. Thus it is clear that $\mathcal{G}_{I_N}(G) = |G|$ for G with at most one vertex.

Assume now that $|G| \in \{2, \dots, N\}$. There exists a vertex u of G such that $G - u$ is connected (take, for instance, u as an endpoint of a diameter of G). Then removing the whole graph or removing $G - u$ are legal moves leading to a graph with at most one vertex. Thus $\mathcal{G}_{I_N}(G) \geq 2$.

Now, if G has $N + 1$ vertices, then every legal move leads to a graph G' having between 1 and N vertices, and thus having a positive Grundy value. Hence $\mathcal{G}_{I_N}(G) = 0$.

Similarly, if G has $N + 2$ vertices, one can play to a graph G' with $N + 1$ vertices since there exists a vertex not disconnecting the graph, thus to a graph with Grundy value 0. But there is no possible move to a graph of Grundy value 1. Finally $\mathcal{G}_{I_N}(G) = 1$. □

This lemma can be extended when one appends a path of size $N + 1$ to G .

Lemma 6. *Let G be a graph, u a vertex of G and $G' = G \bullet_u \bullet P_{N+1}$. We have $\mathcal{G}_{I_N}(G') = |G|$ if $|G| \in \{0, 1\}$, $\mathcal{G}_{I_N}(G') \geq 2$ if $|G| \in \{2, \dots, N\}$, $\mathcal{G}_{I_N}(G') = 0$ if $|G| = N + 1$, and $\mathcal{G}_{I_N}(G') = 1$ if $|G| = N + 2$.*

Proof. Let n be the number of vertices of G . If $n \leq 1$, then G' is a path and the result is true.

If $n \in \{2, \dots, N\}$, then one can play from G' to P_{N+1} by removing G and to $G \bullet_u \bullet P_{N+2-n}$ which has $N + 2$ vertices. By Lemma 5, these two graphs have Grundy values 0 and 1, thus $\mathcal{G}_{I_N}(G') \geq 2$.

Assume now that $n = N + 1$. Let H' be an option of G' . Either $H' = G \bullet_u \bullet P_i$ with $i \in \{1, \dots, N\}$ or $H' = H \bullet_u \bullet P_{N+1}$ where H is an option of G containing u (taking u but not the whole graph G would disconnect G'). In the first case, one can play from H' to G which has Grundy value 0. Thus $\mathcal{G}_{I_N}(H') \neq 0$. In the

second case, as seen before, since H has between 1 and N vertices, we also have $\mathcal{G}_{I_N}(H') \neq 0$. Finally, $\mathcal{G}_{I_N}(G') = 0$.

Finally, assume that $n = N + 2$. As before, the options H' of G' are either of the form $H' = G \overset{\bullet}{\underset{u}{\rightarrow}} P_i$ with $i \in \{1, \dots, N\}$ or $H' = H \overset{\bullet}{\underset{u}{\rightarrow}} P_{N+1}$ where H is an option of G containing u . In particular, one can take for H in the second case the graph G where a vertex not disconnecting G and different from u is removed. This option has Grundy value 0. Thus $\mathcal{G}_{I_N}(G') > 0$. In the first case, one can play to G with Grundy value 1 (by the previous lemma) and thus $\mathcal{G}_{I_N}(H') \neq 1$. In the second case, since H has between 2 and $N + 1$ vertices, we also have $\mathcal{G}_{I_N}(H') \neq 1$. Finally, $\mathcal{G}_{I_N}(G') = 1$. \square

In order to derive periodicity results, we will often prove that G and $G \overset{\bullet}{\underset{u}{\rightarrow}} P_{N+1}$ have the same Grundy value. To prove such a result, a classical way is to prove the equivalent statement that $G + G \overset{\bullet}{\underset{u}{\rightarrow}} P_{N+1}$ is a \mathcal{P} -position. We will generally prove this by proving that any move of the first player can be answered by the second player with a move to a \mathcal{P} -position. The following proposition shows that, somehow, the only case to be addressed is the one where the first player removes vertices in G , and in particular removes the vertex u .

Proposition 7. *Let N be an integer. Let G be a graph and u be a vertex of G . Assume G is minimal in the sense that $\mathcal{G}_{I_N}(G) \neq \mathcal{G}_{I_N}(G \overset{\bullet}{\underset{u}{\rightarrow}} P_{N+1})$ but $\mathcal{G}_{I_N}(G') = \mathcal{G}_{I_N}(G' \overset{\bullet}{\underset{u}{\rightarrow}} P_{N+1})$ for any connected subgraph G' of G containing u . Since $\mathcal{G}_{I_N}(G + G \overset{\bullet}{\underset{u}{\rightarrow}} P_{N+1}) \neq 0$, then there exists a winning move on $G + G \overset{\bullet}{\underset{u}{\rightarrow}} P_{N+1}$. Then every winning move of $G + G \overset{\bullet}{\underset{u}{\rightarrow}} P_{N+1}$ is in the component G , removes the vertex u and leaves at least two vertices.*

Proof. Any move in P_{N+1} can be completed to leave $G + G$ to the first player, which is a \mathcal{P} -position. Any move in $G \overset{\bullet}{\underset{u}{\rightarrow}} P_{N+1}$ leading to $G' \overset{\bullet}{\underset{u}{\rightarrow}} P_{N+1}$ with G' a connected subgraph of G containing u can be replicated in the other component so as to leave $G' + G' \overset{\bullet}{\underset{u}{\rightarrow}} P_{N+1}$, which is a \mathcal{P} -position since G is assumed to be minimal. Now let us consider a move in $G \overset{\bullet}{\underset{u}{\rightarrow}} P_{N+1}$ leading to P_{N+1-i} for some $i, i \geq 0$. This implies that $|G| \leq N - i$. By Observation 3, this implies $g = \mathcal{G}_{I_N}(G) \leq N - i < N + 1 - i$, hence there exists a move from P_{N+1-i} to P_g . In the whole game, the first player gets $G + P_g$ which has Grundy value 0. Thus, if a winning move on $G + G \overset{\bullet}{\underset{u}{\rightarrow}} P_{N+1}$ exists, then this move is on G , and leads to a connected subgraph G' of G . Moreover, if u is still in G' or if the move is taking the whole graph G , then this move can be replicated in the other component by the second player, so as to leave $G' + G' \overset{\bullet}{\underset{u}{\rightarrow}} P_{N+1}$ or P_{N+1} , which is in both cases a \mathcal{P} -position. Finally, if G' is a single vertex v , then the second player can take at the end of P_{N+1} the same number of vertices, that is $|G| - 1$, leaving a component with $N + 2$ vertices. Thus

at the end, using Lemma 5, the two components of the sum have Grundy value 1 and thus the sum is a \mathcal{P} -position. \square

3.2. Simple Stars

In this subsection, we consider the case where G is a simple star to which a path is appended. A simple star is a graph composed of a central vertex connected to a nonnegative number of vertices of degree 1, which we call leaves. We will denote by S_{1^t} the simple star with t leaves. We assume that $N \geq 3$ since the case $N = 2$ is solved in [3].

The periodicity of the Grundy values is an easy consequence of Proposition 7.

Proposition 8. *Let t be a positive integer, u the central vertex of S_{1^t} and $N \geq 3$. For any $k \geq 0$, we have $\mathcal{G}_{I_N}(S_{1^t} \bullet_u \bullet P_k) = \mathcal{G}_{I_N}(S_{1^t} \bullet_u \bullet P_{k \bmod N+1})$. In particular, the function $f_{I_N, S_{1^t}, u}$ is purely periodic with period $N + 1$.*

Proof. Let $G = S_{1^t} \bullet_u \bullet P_k$ and u' be the endpoint of P_k in G ($u' = u$ if $k = 0$). Then $S_{1^t} \bullet_u \bullet P_{k+N+1}$ can be written $G \bullet_{u'} \bullet P_{N+1}$. We need to prove that $G + G \bullet_{u'} \bullet P_{N+1}$ is a \mathcal{P} -position for any k and t .

Assume that this is not true and let (k, t) be the smallest pair of integers (in lexicographic order) such that $G + G \bullet_{u'} \bullet P_{N+1}$ is an \mathcal{N} -position.

Let G' be a connected proper subgraph of G containing u' . Either G' is a path with endpoint u' , or $G' = S_{1^{t'}} \bullet_u \bullet P_k$ with $t' < t$. By minimality of (k, t) , and since the Grundy values of paths are periodic, then $G' + G \bullet_{u'} \bullet P_{N+1}$ is a \mathcal{P} -position.

Thus we can apply Proposition 7 on G , and the only possible winning move in $G + G \bullet_{u'} \bullet P_{N+1}$ is a move in the component G that is taking u' and leaving at least two vertices. This corresponds to a move from G to $G' = S_{1^t} \bullet_u \bullet P_{k'}$ with $k' < k$. Then the second player can play in the component $G \bullet_{u'} \bullet P_{N+1}$ to $S_{1^t} \bullet_u \bullet P_{k'+N+1}$ by taking $k - k'$ vertices on the path. By minimality of k , the resulting position is a \mathcal{P} -position and thus the move from G to G' was not a winning move, a contradiction. \square

Since the function is purely periodic, if one wants to know the Grundy value of $S_{1^t} \bullet_u \bullet P_k$ we just need to compute the values for $k \leq N$. The values for $k = 0$, which are actually the Grundy values of S_{1^t} , are given in the following lemma.

Lemma 9. *Let $t \geq 1$ be a positive integer and $N \geq 3$. We have*

$$\mathcal{G}_{I_N}(S_{1^t}) = \begin{cases} 2 & \text{if } t \leq N - 1 \text{ and } t \text{ is odd} \\ 3 & \text{if } t \leq N - 1 \text{ and } t \text{ is even} \\ 0 & \text{if } t = N + i \text{ with } i \text{ even} \\ 1 & \text{if } t = N + i \text{ with } i \text{ odd.} \end{cases}$$

Proof. We use induction on t . The base cases are $t = 1$ and $t = 2$ for which S_{1^t} is simply P_2 and P_3 respectively and the result holds by Lemma 4.

Assume now that $t \geq 3$. We consider three cases:

Case 1: t is odd, $3 \leq t \leq N - 1$

We prove that $S_{1^t} + P_2$ is a \mathcal{P} -position. We examine every option of the first player:

- If the first player plays to either $S_{1^t} + P_1$ or $P_1 + P_2$, then the second player answers by playing to $P_1 + P_1$ which is a \mathcal{P} -position;
- If the first player plays to either P_2 or S_{1^t} , then the second player answers by removing all vertices of the remaining graph;
- If the first player takes one leaf from S_{1^t} , then the second player answers by taking another leaf from S_{1^t} , leaving $S_{1^{t-2}} + P_2$. By induction hypothesis, this is a \mathcal{P} -position.

Case 2: t is even, $4 \leq t \leq N - 1$

We prove that $S_{1^t} + P_3$ is a \mathcal{P} -position. We examine every option of the first player:

- If the first player plays to $S_{1^t} + P_2$ (resp. to $S_{1^{t-1}} + P_3$), then the second player answers by taking one leaf from S_{1^t} (resp. by reducing P_3 to P_2), leaving $S_{1^{t-1}} + P_2$, which is a \mathcal{P} -position by induction hypothesis;
- If the first player plays to either P_3 or S_{1^t} , then the second player answers by playing by removing all vertices of the remaining graph (this is always possible since $t \geq 4$ and $t \leq N - 1$ implies $N \geq 5$);
- If the first player plays to either $S_{1^t} + P_1$ or $P_1 + P_3$, then the second player answers by playing to $P_1 + P_1$ which is a \mathcal{P} -position.

Case 3: $t \geq N$

We write $t = N + i$ with $i \geq 0$. We use induction on i to prove that $\mathcal{G}(S_{1^t}) = i \bmod 2$.

If $i = 0$, then S_{1^t} has $N + 1$ vertices. By Lemma 5, this graph has Grundy value 0.

If $i > 0$, then there is only one move from S_{1^t} , which is removing one leaf, leaving $S_{1^{t-1}}$. Thus, we have:

$$\begin{aligned} \mathcal{G}(S_{1^t}) &= \text{mex}(\mathcal{G}(S_{1^{t-1}})) && \text{by definition of } \mathcal{G} \\ &= \text{mex}(i - 1 \bmod 2) && \text{by induction hypothesis} \\ &= i \bmod 2. \end{aligned}$$

□

One can get the values for $k > 0$ from these first values by recursive computation. For instance, Table 1 gives the Grundy values for $CSG(I_4)$ on $S_{1^t,k}$ for $t \leq 10$ and $k \leq 8$.

$k \backslash t$	0	1	2	3	4	5	6	7	8	9	10
0	1	2	3	2	0	1	0	1	0	1	0
1	2	3	2	0	1	0	1	0	1	0	1
2	3	4	0	1	2	3	2	3	2	3	2
3	4	0	1	4	3	2	3	2	3	2	3
4	0	1	5	3	4	5	4	5	4	5	4
5	1	2	3	2	0	1	0	1	0	1	0
6	2	3	2	0	1	0	1	0	1	0	1
7	3	4	0	1	2	3	2	3	2	3	2
8	4	0	1	4	3	2	3	2	3	2	3

Table 1: The Grundy values of $S_{1^t,k}$ for the game $CSG(I_4)$, for $t \leq 10$ and $k \leq 8$.

3.3. Subdivided Stars With Three Paths

We now focus on subdivided stars with three paths, with one of the paths of size 1. We recall that we denote by $S_{1,k,\ell}$ the subdivided star with three paths of sizes 1, k and ℓ , respectively. Technically speaking, all degree 1 vertices of $S_{1,k,\ell}$ are leaves, but, for the sake of simplicity, in the sequel we will denote the degree 1 vertex corresponding to the path of size 1 as *the leaf*. Conversely, we will use the word *path* only to denote either P_k or P_ℓ , even if, technically speaking, P_1 is also a path. We prove that the Grundy values are purely periodic with period $N + 1$ except for some values for which there is a preperiod $N + 1$. More precisely, we will prove in this subsection the following theorem.

Theorem 10. *Let $N \geq 3$, k, ℓ be two nonnegative integers. The Grundy value of the subdivided star $S_{1,k,\ell}$ for the game $CSG(I_n)$ is*

$$\mathcal{G}_{I_N}(S_{1,k,\ell}) = \begin{cases} \mathcal{G}_{I_N}(S_{1,(k \bmod (N+1))+N+1,N}) & \text{if } k > N \text{ and } \ell \equiv N \pmod{N+1}, \\ \mathcal{G}_{I_N}(S_{1,N,(\ell \bmod (N+1))+N+1}) & \text{if } \ell > N \text{ and } k \equiv N \pmod{N+1}, \\ \mathcal{G}_{I_N}(S_{1,k \bmod (N+1),\ell \bmod (N+1)}) & \text{otherwise.} \end{cases}$$

Thanks to this theorem, for a fixed N there are only $O(N^2)$ values to compute.

Corollary 11. *Let k, ℓ be two nonnegative integers. Then there exists an algorithm computing the Grundy value of the subdivided star $S_{1,k,\ell}$ for the game $CSG(I_N)$, and this algorithm runs in time $\theta(N^2)$.*

However, all of these values are needed to prove Theorem 10. First, we give the Grundy values of $S_{1,k,\ell}$ when $\ell, k < N$.

Lemma 12. *Let k, ℓ be nonnegative integers. If $k, \ell < N$, then the Grundy value of the subdivided star $S_{1,k,\ell}$ for the game $CSG(I_n)$ is*

$$\mathcal{G}_{I_N}(S_{1,k,\ell}) = \begin{cases} k + \ell & \text{if } k + \ell \leq N - 2 \text{ and } k, \ell \text{ odd} \\ k + 1 & \text{if } k + \ell \leq N - 2 \text{ and } k = \ell \neq 0 \text{ even} \\ k + \ell + 2 \pmod{N + 1} & \text{otherwise} \end{cases}$$

These values are compiled in Table 2.

$\ell \backslash k$	0	1	2	3	4	5	...	$N - 4$	$N - 3$	$N - 2$	$N - 1$
0	2	3	4	5	6	7	...	$N - 2$	$N - 1$	N	0
1	3	2	5	4	7	6	...	$N - 3$ if N even $N - 1$ if N odd	N if N even $N - 2$ if N odd	0	1
2	4	5	3	7	8	9	...	N	0	1	2
3	5	4	7	6	9	8	...	0	1	2	3
4	6	7	8	9	5	11	...	1	2	3	4
...
$N - 2$	N	0	1	2	3	4	...	$N - 5$	$N - 4$	$N - 3$	$N - 2$
$N - 1$	0	1	2	3	4	5	...	$N - 4$	$N - 3$	$N - 2$	$N - 1$

Table 2: Grundy values of $S_{1,k,\ell}$ for the game $CSG(I_n)$. The values where $\mathcal{G}_{I_N}(S_{1,k,\ell}) \neq |S_{1,k,\ell}| \pmod{N + 1}$ are bolded.

Proof. In order to prove this result, we use induction on (k, ℓ) with the lexicographic order. If k or $\ell = 0$, $S_{1,k,\ell}$ is simply the path $P_{\ell+k+2}$ on $\ell + k + 2$ vertices, having Grundy value $k + \ell + 2 \pmod{N + 1}$.

Assume now that $k, \ell \neq 0$, and assume that the formula holds for all $(i, j) < (k, \ell)$. We prove that the Grundy value of $S_{1,k,\ell}$ satisfies the formula of Lemma 12.

By symmetry, we can assume that $k \leq \ell$.

Case 1: $k + \ell \leq N - 2$.

From $S_{1,k,\ell}$, then there are exactly three types of possible moves:

- Type 1 move: removing the leaf, leaving $P_{k+\ell+1}$ which has Grundy value $k + \ell + 1$ (only one such move).
- Type 2 move: removing the leaf, the central vertex, one of the two paths and some vertices from the other path, leaving a path P_i , for $i \in J_0, \ell K$ (hence Type 2 moves can have all the Grundy values between 0 and ℓ).
- Type 3 move: removing some vertices from one of the paths, leaving $S_{1,i,\ell}$ for $i \in J_0, k - 1K$, or leaving $S_{1,k,j}$ for $j \in J_0, \ell - 1K$, whose Grundy values may be computed by induction.

Depending on the parities of k and ℓ , the Grundy values of Type 3 moves may differ. The following subcases are dedicated to computing these Grundy values.

Subcase 1.1: k, ℓ are odd.

By induction hypothesis, the options $S_{1,i,\ell}$ with $i \in J0, k - 1K$ have Grundy values:

- $\ell + i$ when i is odd, giving all even values between $\ell + 1$ and $\ell + k - 2$;
- $\ell + i + 2$ when i is even, giving all odd values between $\ell + 2$ and $\ell + k + 1$.

That is to say, these options have all the values between $\ell + 1$ and $\ell + k - 1$, as well as value $\ell + k + 1$. Similarly, the options $S_{1,k,j}$ with $j \in J0, \ell - 1K$ have all the Grundy values between $k + 1$ and $\ell + k - 1$, as well as value $\ell + k + 1$.

Finally, among the options of $S_{1,k,\ell}$, we have all the values between 0 and $\ell + k - 1$, except the value $k + \ell$, hence $\mathcal{G}(S_{1,k,\ell}) = k + \ell$.

Subcase 1.2: $k = \ell$ and k is even.

By the induction hypothesis, the options $S_{1,i,k}$ have Grundy values $k + i + 2 > k + 1$ for all $i \in J0, k - 1K$. Type 2 moves imply that $\mathcal{G}(S_{1,k,k}) \geq k + 1$. Since no option of $S_{1,k,k}$ has Grundy value $k + 1$, this means that $\mathcal{G}(S_{1,k,k}) = k + 1$.

Subcase 1.3: $k + \ell \leq N - 2$, k odd, ℓ even.

By the induction hypothesis, the options $S_{1,i,\ell}$ with $i \in J0, k - 1K$ have Grundy values $\ell + i + 2$, giving all the values between $\ell + 2$ and $\ell + k + 1$ (since $i < k < \ell$ the case $\ell = i$ does not happen). As before, the options $S_{1,k,j}$ with $j \in J0, j - 1K$ give all the values between $k + 1$ and $k + \ell$ and in particular the value $\ell + 1$ since $k \geq 1$. Finally, all the values up to $\ell + k + 1$ appear as options, except the value $\ell + k + 2$, leading to $\mathcal{G}(S_{1,k,\ell}) = k + \ell + 2$.

Subcase 1.4: $k + \ell \leq N - 2$, k even, ℓ odd.

By the induction hypothesis, the options $S_{1,i,\ell}$ give all the values between $\ell + 1$ and $\ell + k$. Hence all the values between 0 and $\ell + k$ are present in the options. Remember that value $k + \ell + 1$ is done by the Type 1 move. Finally, the Grundy value of options $S_{1,k,j}$ are smaller than $k + \ell + 1$, and we have again $\mathcal{G}(S_{1,k,\ell}) = k + \ell + 2$.

Subcase 1.5: $k + \ell \leq N - 2$, k even, ℓ even, $k \neq \ell$.

The options $S_{1,i,\ell}$ give all the values between $\ell + 2$ and $\ell + k + 1$. The value $\ell + 1$ is given by option $S_{1,k,\ell-k-1}$ (which exists since $k < \ell$). Thus all the values between 0 and $\ell + k + 1$ are present in the options. Finally, the Grundy value of options $S_{1,k,j}$ are smaller than $k + \ell + 1$. Thus, we have again $\mathcal{G}(S_{1,k,\ell}) = k + \ell + 2$.

Case 2: $k + \ell \geq N - 1$ and $1 \leq k, \ell \leq N - 1$.

Let $j = k + \ell + 2 - N + 1$. Then $0 \leq j \leq N - 1$. We prove that $S_{1,k,\ell} + P_j$ is a \mathcal{P} -position.

Assume that this is not true and take the smallest j for which this result is not true.

If the first player takes c vertices in $S_{1,k,\ell}$ then the second player can always take $N + 1 - c$ vertices in the same component and move to P_j . Then the sum is a \mathcal{P} -position. Indeed, if the first player takes c vertices on the path of size k and $c \leq k$, then the second player can take the $k - c \leq N - 2$ vertices remaining on the path of size k , the central vertex, the leaf, and some vertices on the path of size ℓ to obtain P_j . If the first player plays from $S_{1,k,\ell}$ to a path, this one has $k + \ell + 2 - c > j$ vertices and the second player can take $N + 1 - c$ vertices on it to go to P_j .

Assume now that the first player plays c vertices on P_j to $P_{j'}$. By definition of j , we must have either $k \geq j$ or $\ell \geq j$. Assume that $k \geq j$. Then the first player takes c vertices on the path of size k to play to $S_{1,k',j}$. We still have $k' + \ell \geq N - 1$ and by minimality, $S_{1,k',\ell} + P_{j'}$ is a losing position. \square

The following lemma gives the periodicity of values 0 and 1. It completes Lemma 5 for $S_{1,k,\ell}$.

Lemma 13. *Let k, ℓ be two integers.*

If $|S_{1,k,\ell}| = 0 \pmod{N + 1}$ then $\mathcal{G}_{I_N}(S_{1,k,\ell}) = 0$.

If $|S_{1,k,\ell}| = 1 \pmod{N + 1}$ then $\mathcal{G}_{I_N}(S_{1,k,\ell}) = 1$.

Otherwise, $\mathcal{G}_{I_N}(S_{1,k,\ell}) > 1$.

Proof. We prove the whole lemma by induction on (k, ℓ) (in the lexicographic order). Note that this result is trivially true for paths. By Lemma 5, the result is true if $|S_{1,k,\ell}| = k + \ell + 2 \leq N + 2$.

Let k, ℓ with $k + \ell + 2 > N + 2$. Assume first that $k + \ell + 2 = 0 \pmod{N + 1}$. All the moves lead to a graph which is a path or a subdivided star with a number of vertices not congruent to 0 modulo $N + 1$, and thus, by induction the Grundy value is positive. Hence, $\mathcal{G}_{I_N}(S_{1,k,\ell}) = 0$.

Assume now that $k + \ell + 2 = 1 \pmod{N + 1}$. As in the previous case, all the moves lead to a graph which is a path or a subdivided star with a number of vertices not congruent to 1 modulo $N + 1$, and by induction the Grundy value is not equal to 1. Furthermore, it is always possible to remove one vertex, leading to a graph with 0 vertices modulo $N + 1$ that has by induction Grundy value 0. Hence, $\mathcal{G}_{I_N}(S_{1,k,\ell}) = 1$.

Finally, assume that $k + \ell + 2 = i \pmod{N + 1}$ with $i > 1$. If one cannot remove i vertices, it means that $k = \ell = i - 1$. Hence the total number of vertices is $2i$ and must be congruent to i modulo $N + 1$. Since $i \neq 0$, this is not possible. Hence one can remove i vertices and then the resulting graph has Grundy value 0. Similarly, if one cannot remove $i - 1$ vertices, it means that $k = \ell = i - 2$. Hence the total number of vertices is $2i - 2$ and must be congruent to i modulo $N + 1$. It means that $i = 2 \pmod{N + 1}$ and so $i = 2$. But then the graph is just K_2 , which is not

possible since there are at least $N + 2$ vertices. Hence one can always remove $i - 1$ vertices and the resulting graph has Grundy value 1. Finally, $\mathcal{G}_{I_N}(S_{1,k,\ell}) > 1$. \square

We now prove the "otherwise" part of Theorem 10, which is the simplest case when both paths can be reduced modulo $N + 1$.

Lemma 14. *Let $N \geq 3$, and let k and ℓ be two nonnegative integers satisfying the following property:*

$$(P) \quad k \leq N \text{ or } \ell \leq N \text{ or } \ell \text{ and } k \text{ are not congruent to } N \text{ modulo } N + 1.$$

Then, we have $\mathcal{G}_{I_N}(S_{1,k,\ell}) = \mathcal{G}_{I_N}(S_{1,k \bmod (N+1), \ell \bmod (N+1)})$.

Proof. Let k, ℓ, N be integers satisfying (P). Let $k_0 = k \bmod N + 1$ and $\ell_0 = \ell \bmod N + 1$.

We want to prove that $S_{1,k,\ell} + S_{1,k_0,\ell_0}$ is a \mathcal{P} -position. Consider a minimal counterexample, when minimizing $k + \ell$. We consider all the possible winning moves for the first player.

Case 1: The first player plays in the first component $S_{1,k,\ell}$.

Subcase 1.1: The first player takes c vertices in the path of size ℓ leading to $S_{1,k,\ell'}$ with $\ell' < \ell$.

If $\ell > \ell_0$, then the second player can answer in the first component by $S_{1,k,\ell-(N+1)}$. Since $\ell - (N + 1) = \ell_0 \bmod N + 1$ and since $k, \ell - (N + 1)$ satisfy (P), by minimality the sum is a \mathcal{P} -position.

Assume now that $\ell = \ell_0$. Then the second player answers in the second component to $S_{1,k_0,\ell'}$. Since k, ℓ' satisfy (P) ($\ell' \leq N$), then the sum is by minimality a \mathcal{P} -position.

By permuting k and ℓ , we can prove the symmetric case.

Subcase 1.2: The first player removes the leaf and thus move the first component to $P_{k+\ell+1}$. Then the second player can move the second component to $P_{k_0+\ell_0+1}$. Since $k = k_0 \bmod (N + 1)$ and $\ell = \ell_0 \bmod (N + 1)$, these two paths have the same Grundy value and their sum is a \mathcal{P} -position.

Subcase 1.3: The first player removes the leaf, the path of size k , the central vertex and some vertices on the path of size ℓ , leading the first component to P_i with $i \leq \ell$. Then $k = k_0$ and the second player can remove the same number of vertices, leading to $P_{i-(\ell-\ell_0)}$, which has the same Grundy value as P_i .

By permuting k and ℓ we get the symmetric case.

Case 2: The first player plays in the second component S_{1,k_0,ℓ_0} .

Subcase 2.1: The first player takes c vertices in the path of size ℓ_0 leading to S_{1,k_0,ℓ'_0} with $\ell'_0 < \ell_0$.

Let $\ell' = \ell - c$. Then k, ℓ' satisfy (P) . Indeed, $\ell' \not\equiv N \pmod{N+1}$ since $\ell' = \ell'_0 \pmod{N+1}$ and $0 \leq \ell'_0 < N$. Therefore, if the second player answers by playing in the first component to $S_{1,k,\ell'}$ we get a \mathcal{P} -position by minimality.

By permuting k and ℓ , we can prove the symmetric case.

Subcase 2.2: The first player removes the leaf and thus moves the second component to $P_{k_0+\ell_0+1}$. Then the second player can move the first component to $P_{k+\ell+1}$. Since $k = k_0 \pmod{N+1}$ and $\ell = \ell_0 \pmod{N+1}$, then these two paths have the same Grundy value and their sum is a \mathcal{P} -position.

Subcase 2.3: The first player removes the leaf, the path of size k_0 , the central vertex and some vertices on the path of size ℓ_0 , leading the first component to P_i with $i \leq \ell_0$. Let c be the total number of vertices taken by the first player. If $k = k_0$, then the second player can play in the first component to $P_{i+\ell-\ell_0}$, which has the same Grundy value as P_i . Hence we can assume that $k > k_0$. Consider the position $S_{1,k-c,\ell}$.

Let $k'_0 = k - c \pmod{N+1}$. We have $k'_0 = k_0 - c + N + 1$ and $i + c = k_0 + \ell_0 + 2$. Then $k'_0 + \ell_0 = k_0 - c + N + 1 + \ell_0 = i + N + 1$. In particular, $k'_0 + \ell_0 \geq N - 1$. Hence, we are in the last case of Lemma 12 and, by induction,

$$\mathcal{G}(S_{1,k-c,\ell}) = \mathcal{G}(S_{1,k'_0,\ell_0}) = k'_0 + \ell_0 + 2 \pmod{N+1} = i = \mathcal{G}(P_i).$$

By permuting k and ℓ , we can prove the symmetric case. □

We will now study the case where (P) is not satisfied, which corresponds to the “if” parts of Theorem 10. Since both parts are symmetrical, we only need to prove one of them.

Lemma 15. *Let $N \geq 3$, k, ℓ be two nonnegative integers such that $k > N$ and $\ell \equiv N \pmod{N+1}$. Then, we have $\mathcal{G}_{I_N}(S_{1,k,\ell}) = \mathcal{G}_{I_N}(S_{1,(k \bmod (N+1))+N+1,N})$.*

Proof. We will first prove that the options $S_{1,i,N}$ with $i < N - 2$ of $S_{1,k,N}$ (obtained by playing on the branch of size k) are not useful to compute $\mathcal{G}(S_{1,k,N})$, when $N < k < 2N$. In order to prove this, we show how to compute the Grundy value of $S_{1,k,N}$ for $k \in \mathbb{J}1, 2N\mathbb{K}$.

$$\text{Let } r_N = \left\lfloor \frac{N}{2} \right\rfloor \text{ if } N \equiv 2, 3 \pmod{4}, \text{ and } r_N = \left\lfloor \frac{N-2}{2} \right\rfloor \text{ otherwise.}$$

This first technical claim will let us make explicit the Grundy values of the options of $S_{1,k,N}$ reached when playing on the path of length N .

Claim 15.1. *Let $k \in \mathbb{J}1, 2N - 1\mathbb{K}$ be a positive integer with $k \notin \{N - 1, N, N + 1\}$, and $k_0 = k \pmod{N+1}$.*

1. *If $k_0 \in \mathbb{J}1, r_N\mathbb{K}$ and k_0 is even, then $S_{1,k,N}$ has options of all Grundy values in the interval $\mathbb{J}0, N\mathbb{K}$, except $2k_0 + 2$, by removing vertices from the path of length N .*

2. If $k_0 \in Jr_N + 1, N - 2K$ and k_0 is even, then $S_{1,k,N}$ has options of all Grundy values in the interval $J0, NK$, except $k_0 + 1$, by removing vertices from the path of length N .
3. If k_0 is odd, then $S_{1,k,N}$ has options of all Grundy values in the interval $J0, NK$, except $N - 1$ (if N is odd), or N (if N is even), by removing vertices from the path of length N .

Proof. Let $k \in J1, N - 2K$ be a positive integer. We will make use of the Grundy values given in Lemma 12.

If $k \in J1, r_N K$ is even, then every subdivided star $S_{1,k,i}$ (with $i \in J0, N - 1K$) has Grundy value $i + k + 2 \pmod{N + 1}$, except the subdivided star $S_{1,k,k}$ which has Grundy value $k + 1$. Note that we have $2k + 2 \leq N - 2$ (by definition of r_N and since k is even). Thus, the subdivided star $S_{1,k,N}$ has options with all the Grundy values in the set $\{k + 2 \pmod{N + 1}, \dots, k + 1 + N \pmod{N + 1}\}$, except $2k + 2$, and an option of Grundy value $k + 1$. This proves the first part of the claim.

Now, if $k \in Jr_N + 1, N - 2K$ is even, then every subdivided star $S_{1,k,i}$ (with $i \in J0, N - 1K$) has Grundy value $i + k + 2 \pmod{N + 1}$. Thus, the subdivided star $S_{1,k,N}$ has options with all the Grundy values in the set $\{k + 2 \pmod{N + 1}, \dots, k + 1 + N \pmod{N + 1}\}$, proving the second part of the claim.

Finally, if k is odd, then the subdivided stars $S_{1,k,i}$ have the following Grundy values: $i + k$ if $i < N - k - 1$ and i is odd; and $i + k + 2 \pmod{N + 1}$ otherwise. Thus, the subdivided star $S_{1,k,N}$ has options with all the Grundy values in the set $\{0, \dots, k\}$ (when $i \geq N - k - 1$), and in the set $\{k + 1, \dots, N - 2\}$. Furthermore, if N is even then it has an option of Grundy value $N - 1$, and if N is odd then it has an option of Grundy value N . Indeed, the Grundy values of $S_{1,k,0}, S_{1,k,1}, S_{1,k,2}, \dots, S_{1,k,N-k-4}, S_{1,k,N-k-3}, S_{1,k,N-k-2}$ are $k + 2, k + 1, k + 4, \dots$ and either $\dots, N - 4, N - 1, N - 2$ if N is even or $\dots, N - 2, N - 3, N$ if N is odd. This proves the third part of the claim.

If $k \in JN + 2, 2N - 1K$, then the result holds by Lemma 14: the options of $S_{1,k,N}$ when removing vertices from the path of length N have the same Grundy values as the equivalent options of $S_{1,k-(N+1),N}$. \square

We are now ready to compute the values of $\mathcal{G}(S_{1,k,N})$ for $k \in J1, 2NK$.

If $k = a(N + 1) + b$ with $a \geq 0$ and $b \in J1, N - 1K$, then let x_k be the number of subdivided stars $S_{1,i,N}$ with $i \in Ja(N + 1) + 1, k - 1K$ such that $\mathcal{G}(S_{1,i,N}) > N$.

Claim 15.2. *Let $N \geq 3$ be a nonnegative integer, and $k \in J1, 2NK, k \notin \{N, N + 1\}$. Let $m = \text{mex}(\{\mathcal{G}(S_{1,k,i}) \mid i < N\})$. We have the following:*

$$\mathcal{G}(S_{1,k,N}) = \begin{cases} N & \text{if } k = N - 1 \text{ or } k = 2N \\ N - 1 & \text{if } k = N - 2 \text{ or } k = 2N - 1 \\ N + x_k + 1 & \text{if } k \in J1, r_N K \text{ or } m \geq N - 1 \\ m & \text{otherwise.} \end{cases}$$

Proof. We prove the result by way of contradiction. Assume that $k \in J1, 2NK$ is the smallest positive integer such that the result does not hold. Let $k_0 = k \bmod (N+1)$. From $S_{1,k,N}$, there are four kinds of moves:

- Type 1 move: removing the leaf, leaving P_{N+1+k} which has Grundy value $k \bmod (N+1)$ (thus this option will never lead to a contradiction);
- Type 2 move: removing vertices from the path of length N , leaving stars $S_{1,k,i}$ for $i \in J0, N-1K$;
- Type 3 move: removing vertices from the path of length k , leaving stars $S_{1,i,N}$ for $i \in Jmax(0, k-N), k-1K$;
- Type 4 move: if $k \leq N-2$, removing the path of length k , the leaf, the central vertex, and some vertices from the path of length N .

First, note that if $k \geq N+1$, then $x_k \leq x_{k-(N+1)}$. Indeed, by minimality of k , there are at most as many subdivided stars $S_{1,i,N}$ with Grundy values greater than N when $i \in JN+2, k-1K$ as when $i \in J1, k-(N+1)-1K$.

Observe that if $k = N$ (resp. $k = N+1$) then we have $|S_{1,N,k}| = 2N+2$ (resp. $|S_{1,N,k}| = 2N+3$) and by Lemma 13 we have $\mathcal{G}(S_{1,N,k}) = 0$ (resp. $\mathcal{G}(S_{1,N,k}) = 1$). So $k \notin \{N, N+1\}$.

Assume that $k_0 = N-1$, then by Lemmas 12 and 14, Type 2 moves leave subdivided stars with all Grundy values in $J0, N-1K$, so $\mathcal{G}(S_{1,k,N}) \geq N$. Furthermore, Type 3 moves will leave subdivided stars with Grundy values either smaller or greater than N by minimality of k . Thus, $\mathcal{G}(S_{1,k,N}) = N$, a contradiction. So $k \notin \{N-1, 2N\}$.

Now let $k \in J1, 2N-1K$, $k \notin \{N-1, N, N+1\}$. Assume first that k_0 is odd. Then, by Claim 15.1, the Type 2 moves leave subdivided stars with all Grundy values in $J0, NK$, except $N-1$ or N , depending on the parity of N .

Now if $k_0 < N-2$, then there are two cases:

1. If $k < N-2$ then $S_{1,k,N}$ has options of Grundy values $N-1$ and N by Type 4 moves: leaving P_{N-1} requires removing $k+2+1 \leq N$ vertices, and leaving P_N requires removing $k+2 < N$ vertices.
2. If $k \in JN+2, 2N-2K$, then Type 3 moves allow to reach $S_{1,N-2,N}$ and $S_{1,N-1,N}$, which have Grundy values $N-1$ and N .

Thus, the Grundy value of $S_{1,k,N}$ is greater than N . Furthermore, the Type 3 moves allow us to reach x_k options of Grundy values $N+1, \dots, N+x_k$ by definition of x_k . And, if $k \in JN+2, 2N-1K$, since $x_k \leq x_{k-(N+1)}$, the subdivided star $S_{1,i,N}$ such that $\mathcal{G}(S_{1,i,N}) = N+x_k+1$ verifies $i \leq k-(N+1)$, and as such is not an option of $S_{1,k,N}$. This implies that $\mathcal{G}(S_{1,k,N}) = N+x_k+1$, a contradiction. Thus if k_0 is odd then $k_0 = N-2$.

If $k_0 = N - 2$, then N is odd and $S_{1,k,N}$ has no option of Grundy value $N - 1$ from Type 2 moves. Furthermore, Type 3 moves cannot lead to an option of Grundy value $N - 1$. Indeed, those options have either P_{N-1} (if $k = N - 2$) or $S_{1,N-2,N}$ (if $k = 2N - 1$) as an option, and those have Grundy value $N - 1$ by minimality of k . Those cannot be options of $S_{1,k,N}$ since it would require removing $N + 1$ vertices. Finally, if $k = N - 2$ then Type 4 moves can only leave P_N . Thus, $\mathcal{G}(S_{1,k,N}) = N - 1$, a contradiction.

This implies that k_0 is even. Assume first that $k_0 \in J1, r_N K$. Then by Claim 15.1, Type 2 leave subdivided stars with all Grundy values in $J0, NK$, except $2k + 2$, thus $\mathcal{G}(S_{1,k,N}) \geq 2k + 2$. We recall that $2k + 2 \leq N - 2$. There are two cases:

1. If $k \in J1, r_N K$, then the subdivided star $S_{1,k,N}$ has P_{2k+2} as an option, by removing the path of length k , the leaf, the central vertex and $N - (2k + 2)$ vertices from the path of length N . This move removes $N - k$ vertices, so this option is always available. Thus, the star $S_{1,k,N}$ has options of all Grundy values in $J0, NK$. Since Type 3 moves enable to reach x_k options of Grundy values $N + 1, \dots, N + x_k$ by definition of x_k , we have $\mathcal{G}(S_{1,k,N}) = N + x_k + 1$, a contradiction.
2. If $k \in JN - 2, N + 1 + r_N K$, then by the minimality of k , no option of $S_{1,k,N}$ has Grundy value $2k_0 + 2$: the only options with a Grundy value smaller than N have Grundy values either of the form $2i + 2$ and are smaller than $2k_0 + 2$, or of the form $i + 1$ with i even, and thus are odd and different from $2k_0 + 2$. All this implies that $\mathcal{G}(S_{1,k,N}) = 2k_0 + 2$, a contradiction.

Thus, we have $k_0 \in Jr_N + 1, N - 2K$. By Claim 15.1, the second kind of move leaves stars with all Grundy values in $J0, NK$, except $k + 1$, thus $\mathcal{G}(S_{1,k,N}) \geq k + 1$. The third kind of move can never leave a star with Grundy value $k + 1$. Indeed, if $k \in Jr_N + 1, N - 2K$ then by minimality of k , if an option by the third kind of move has a Grundy value smaller than N then it is also smaller than $k + 1$. Furthermore, if $k \in JN + 2 + r_N, 2N - 1K$ then any option by the third kind of move has $S_{1,k_0,N}$ as an option, which implies that all these options have a Grundy value different from $k_0 + 1$. Finally, if $k \in Jr_N + 1, N - 2K$ then the fourth kind of move cannot leave P_{k+1} since it would require removing $k + 2 + N - (k + 1) = N + 1$ vertices, which is impossible. Thus, the star $S_{1,k,N}$ has no option of Grundy value $k + 1$, and as such we have $\mathcal{G}(S_{1,k,N}) = k + 1$, a contradiction.

All of this implies that no such k exists, so the claim is proven. □

We now prove the lemma. Let k, ℓ be two nonnegative integers such that $k > N$ and $\ell \equiv N \pmod{N + 1}$. Let $k_0 = k \pmod{N + 1} + N + 1$.

A consequence of the previous proof is that the options $S_{1,i,N}$ with $i < N - 2$ of $S_{1,k_0,N}$ (obtained by playing on the path of size k_0) are not useful to compute $\mathcal{G}(S_{1,k_0,N})$.

We prove the result by induction on $k + \ell$. If $\ell = N$ and $k = N + 1$ the result is clearly true.

Compare the options of $S_{1,k,\ell}$ and $S_{1,k_0,N}$. By Lemma 14, options $S_{1,k,\ell-i}$ and $S_{1,k_0,N-i}$ have the same Grundy values. By induction and thanks to Claim 15.2, options $S_{1,k-i,\ell}$ and $S_{1,k_0-i,N}$, if $i \leq k_0 + 2$, have the same Grundy values. Options $P_{k+\ell+1}$ and P_{k_0+N+1} have the same Grundy values by periodicity on the path (Lemma 4).

Thus, the only different options are $S_{1,k-i,\ell}$ and $S_{1,k_0-i,N}$ for $k_0 + 2 < i \leq N$, if $k > k_0$ (if $k = k_0$, then they are the same by Lemma 14 and thus we are done). By the previous remark, the second ones are not used to compute $\mathcal{G}(S_{1,k_0,N})$. The first ones are different from $\mathcal{G}(S_{1,k-(N+1),\ell})$ since one can play from $S_{1,k-i,\ell}$ to $S_{1,k-(N+1),\ell}$. By induction, $\mathcal{G}(S_{1,k-(N+1),\ell}) = \mathcal{G}(S_{1,k_0,N})$ and thus we also have $\mathcal{G}(S_{1,k,\ell}) = \mathcal{G}(S_{1,k_0,N})$. \square

The proof of Theorem 10 follows from Lemmas 14 and 15. Note that the Grundy sequence is not purely periodic in general since, for specific values of N and i , we have $\mathcal{G}_{I_N}(S_{1,N,N+1+i}) \neq \mathcal{G}_{I_N}(S_{1,N,i})$ (for example, $\mathcal{G}_{I_8}(S_{1,8,2}) = 10$ whereas $\mathcal{G}_{I_8}(S_{1,8,11}) = 6$). However, when N is small enough, the "bad cases" do not happen and the sequence is purely periodic. This is the case for $N = 3$. We will see in the next section, that actually the game $CSG(I_3)$ is purely periodic on all the subdivided stars.

3.4. Application: Study of $CSG(1, 2, 3)$ on Subdivided Stars

In this subsection, we use the previous general results to completely solve the game $CSG(1, 2, 3)$ on subdivided stars. Note that we will use the notation \emptyset to denote the null graph.

Theorem 16. *For all $\ell_1, \dots, \ell_t \geq 0$, $t \geq 1$, we have*

$$\mathcal{G}_{I_3}(S_{\ell_1, \dots, \ell_t}) = \mathcal{G}_{I_3}(S_{\ell_1 \bmod 4, \dots, \ell_t \bmod 4}).$$

Proof. We just need to prove that we can remove four vertices on any branch. Let $S = S_{\ell_1, \dots, \ell_t, m}$ and $S' = S_{\ell_1, \dots, \ell_t, m+4}$. We prove that $S + S'$ is a \mathcal{P} -position. If $S \in \{\emptyset, P_1, P_2\}$, then $S' \in \{P_4, P_5, P_6\}$ and the result holds by Lemma 4. Hence we will suppose that $|S| \geq 3$.

We prove the result by way of contradiction. Let u be the leaf of the path of length m in S (if $m = 0$, then u is the central vertex of S). Assume S is minimal in the sense that $\mathcal{G}(S) \neq \mathcal{G}(S')$ but $\mathcal{G}(S_1) = \mathcal{G}(S_1 \overset{u}{\bullet} \bullet P_4)$ for every sub-subdivided star S_1 of S . Note that, by sub-subdivided star, we mean a subdivided star $S_1 = S_{\ell'_1, \dots, \ell'_t}$ with $\ell'_i \leq \ell_i$ for all i , and with at least one i such that $\ell'_i < \ell_i$. By Proposition 7, the only winning move in $S + S'$ is in S , removes the vertex u , and leaves at least two vertices in S .

If u is the central vertex of S , then there are two cases.

1. S is a path of length $k \geq 3$. In this case, u can be a leaf, or at distance 1 or 2 from a leaf:
 - (a) If u is a leaf, then S' is a path and $\mathcal{G}(S) = \mathcal{G}(S')$ by Lemma 4, a contradiction.
 - (b) If u is at distance 1 from a leaf, then $S' = S_{1,k-2,4}$. If $k - 2 \not\equiv 3 \pmod 4$, then by Theorem 10, we have $\mathcal{G}(S_{1,k-2,4}) = \mathcal{G}(P_k)$ and thus $\mathcal{G}(S) = \mathcal{G}(S')$. Otherwise, we have $k \equiv 1 \pmod 4$ and, as such, by Lemma 13 we have $\mathcal{G}(S') = 1 = \mathcal{G}(P_k)$. Both cases are contradictions.
 - (c) If u is at distance 2 from a leaf, then $S' = S_{2,k-3,4}$ and the winning move consists in removing the path of length 2 along with u in S , leaving P_{k-3} . We claim that removing three vertices from the path of length 4 in S' is an equivalent move. Indeed, the move leaves $S_{1,2,k-3}$. If $k - 3 \not\equiv 3 \pmod 4$, then by Theorem 10 and Lemma 12 we have $\mathcal{G}(S_{1,2,k-3}) = \mathcal{G}(S_{1,2,k-3 \bmod 4}) = k + 1 \bmod 4$ (the last equality comes from the fact that $2 + (k - 3 \bmod 4) \geq 2$). Finally, $\mathcal{G}(S_{1,2,k-3}) = \mathcal{G}(P_{k-3})$. Otherwise, by Theorem 10, we have $\mathcal{G}(S_{1,2,k-3}) = \mathcal{G}(S_{1,2,3})$. By computation we have $\mathcal{G}(S_{1,2,3}) = 3 = \mathcal{G}(P_{k-3})$. Both cases are contradictions.
2. $S = S_{1,1,k}$. In this case, the winning move can only be removing the two leaves and u , leaving P_k . We claim that the graph obtained by removing three vertices from the path of length 4 in S' is equivalent to P_k . Indeed, this leaves $S_{1^3,k}$, which is equivalent to $S_{1^3,k \bmod 4}$ by Proposition 8. There are four possible values for $k \bmod 4$:
 - (a) If $k \bmod 4 = 0$ then we have $\mathcal{G}(S_{1^3,k}) = \mathcal{G}(S_{1^3}) = 0$ by Lemma 9.
 - (b) If $k \bmod 4 = 1$ then we have $\mathcal{G}(S_{1^3,k}) = \mathcal{G}(S_{1^4}) = 1$ by Lemma 9.
 - (c) If $k \bmod 4 = 2$ then there are three options for $S_{1^3,2}$ which are S_{1^3} (which has Grundy value 0 by Lemma 9), S_{1^4} (which has Grundy value 1 by Lemma 9) and $S_{1^2,2}$ (which has Grundy value 1 by Lemma 12). Thus $\mathcal{G}(S_{1^3,2}) = 2$.
 - (d) If $k \bmod 4 = 3$ then there are four options for $S_{1^3,3}$ which are S_{1^3} (which has Grundy value 0 by Lemma 9), S_{1^4} (which has Grundy value 1 by Lemma 9), $S_{1^3,2}$ (which has Grundy value 2 by the above subcase) and $S_{1^2,3}$ (which has Grundy value 4 by computation, and using Lemma 12). Thus $\mathcal{G}(S_{1^3,2}) = 3$.

In the four cases, we have $\mathcal{G}(S_{1^3,k \bmod 4}) = k \bmod 4 = \mathcal{G}(P_k)$. Thus the only possible winning move in $S + S'$ actually leads to an \mathcal{N} -position. This is a contradiction.

Assume now that u is not the central vertex, which means that u is a leaf. If the winning move of the first player does not take the central vertex, then the second player can take the same number of vertices in S' in the branch of size $m + 4$. So, necessarily, the winning move takes the central vertex, u , and leaves a path. This means that $S = S_{1,k,1}$ and that the first player plays to P_k . We claim that removing 3 vertices from the path of length 4 is equivalent to P_k . Indeed, the second component becomes $S'_1 = S_{1,k,2}$ and by Theorem 10 and Lemma 12, it has Grundy value $k \bmod 4$.

All the cases lead to a contradiction, which proves that there is no S such that $S + S'$ is an \mathcal{N} -position. Hence, we have $\mathcal{G}(S) = \mathcal{G}(S')$. \square

4. The $CSG(1, 2, 4)$ Game on Subdivided Stars

First note that if $M \not\equiv 0 \pmod{N+1}$, then the game $CSG(I_N \cup \{M\})$ is equivalent to the game $CSG(I_N)$ when those games are played on paths. However, this is not the case when played on graphs, and even on subdivided stars.

Observation 17. *For all $N \geq 2$, there exists $M \not\equiv 0 \pmod{N+1}$, such that there exists a graph G , and a distinguished vertex u in G , such that $\mathcal{G}_L(G) \neq \mathcal{G}_L(G \overset{\bullet}{\underset{u}{\dashv}} P_{N+1})$ where $L = I_N \cup \{M\}$.*

Proof. Let S be a star with $N + 2$ leaves and u as a central vertex, and $M = 2N + 4$. $S + S \overset{\bullet}{\underset{u}{\dashv}} P_{N+1}$ is an \mathcal{N} -position. The strategy for the first player is to empty $S \overset{\bullet}{\underset{u}{\dashv}} P_{N+1}$ as a first move. The second player is left with a forced move on S . After two more forced moves, the first player will be able to empty S . \square

However, some particular games may retain this equivalence. In this section we study the game $CSG(1, 2, 4)$ on subdivided stars and prove the following, which is analogous to Theorem 16.

Theorem 18. *Let $L = \{1, 2, 4\}$. For all $m \geq 0$ and $\ell_1, \dots, \ell_t \geq 0$, $t \geq 1$, we have*

$$\mathcal{G}_L(S_{\ell_1, \dots, \ell_t, m+3}) = \mathcal{G}_L(S_{\ell_1, \dots, \ell_t, m}).$$

In order to prove this theorem, we first derive results for some specific subclasses of subdivided stars, and we then proceed by induction. For the rest of this section, all Grundy values will be computed for the game $CSG(1, 2, 4)$.

First, it is well-known and easy to see that this game is 3-periodic when played on paths.

Lemma 19. *We have $\mathcal{G}(P_n) = |P_n| \bmod 3$, i.e., $\mathcal{G}(P_n) = \overline{012}$, where P_n denotes the path on n vertices.*

Let us begin with some specific small subdivided stars that will be useful in the sequel.

Lemma 20. *We have $\mathcal{G}(G) = |G| \pmod 3$ for all $G \in \mathcal{S}$, with*

$$\mathcal{S} = \{S_{1,1,1}, S_{1,1,2}, S_{1,1,3}, S_{1,1,1,3}, S_{1,2,2}, S_{1,2,3}, S_{1,1,2,2}, S_{1,1,2,3}\}.$$

In addition, we have $\mathcal{G}(S_{1,1,1,1}) = 0$ and $\mathcal{G}(S_{1,1,1,2}) = 3$.

Proof. The proof is straightforward and a consequence of simple case analysis. It is easy to check that $\mathcal{G}(S_{1,1,1})$ is indeed 1, since there are only two possible moves which lead to \emptyset and to the path P_3 , which both have Grundy number 0. As for $S_{1,1,2}$, there are four possible moves leading to paths P_1 and P_3 , and to $S_{1,1,1}$, and the result follows from the application of the mex rule. Similarly, four moves are available from $S_{1,1,3}$, leading to paths and to $S_{1,1,1}$ and $S_{1,1,2}$. In the case $S_{1,1,1,1}$, we have only two possible moves leading to $S_{1,1,1}$ and P_1 , hence $\mathcal{G}(S_{1,1,1,1}) = 0$. From $S_{1,1,1,2}$, four moves are available, leading to a path P_2 and to $S_{1,1,1,1}$, $S_{1,1,1}$, and $S_{1,1,2}$. We use this result to compute $\mathcal{G}(S_{1,1,1,3})$, since one of the four possible moves leads to $S_{1,1,1,2}$, the other leading also to a path and to already known subdivided stars, namely $S_{1,1,1,1}$ and $S_{1,1,3}$. Similarly, there are four possible moves from $S_{1,2,2}$, all leading to already known graphs. There are six moves from $S_{1,2,3}$, again all leading to paths or previously studied subdivided stars. The cases $S_{1,1,2,2}$ and $S_{1,1,2,3}$ are similar: there are, respectively, three and five moves to study, which thankfully all lead to graphs whose Grundy value have been already computed above. \square

Lemma 21. *For all $k \geq 0$, we have $\mathcal{G}(S_{1,1,k}) = |S_{1,1,k}| \pmod 3$, i.e., $(\mathcal{G}(S_{1,1,k}))_{k \in \mathbb{N}} = \overline{012}$.*

Proof. We proceed by induction on k . The cases $k \leq 3$ are all consequences of Lemma 19 and 20. When $k \geq 4$, we can apply Lemma 2 since there are always exactly five moves available, leading to P_{k+2} , P_{k-1} , $S_{1,1,k-1}$, $S_{1,1,k-2}$, and $S_{1,1,k-4}$. Indeed, the lemma can be applied with \mathcal{F} set to the set of all paths together with subdivided stars $S_{1,1,k'}$ such as $k' < k$, so as to get the desired result by induction (with T in the statement of Lemma 2 set to 3 and $\alpha_i = i$ for $i \in \{0, 1, 2\}$). \square

Lemma 22. *For all $k \geq 0$, we have $\mathcal{G}(S_{1,1,1,k}) = \begin{cases} 1 & \text{if } k \equiv 0 \pmod 3 \\ 0 & \text{if } k \equiv 1 \pmod 3 \\ 3 & \text{if } k \equiv 2 \pmod 3 \end{cases}$, i.e., $(\mathcal{G}(S_{1,1,1,k}))_{k \in \mathbb{N}} = \overline{103}$.*

Proof. The small cases $k \leq 3$ are all consequences of Lemma 20. When $k \geq 4$, there are always exactly five possible moves, leading to $S_{1,1,k}$, P_k , $S_{1,1,1,k-1}$, $S_{1,1,1,k-2}$, and $S_{1,1,1,k-4}$. By induction, and thanks to Lemma 19 and 21, we then have:

- If $k \equiv 0 \pmod 3$, then $\mathcal{G}(S_{1,1,1,k})$ is computed as $\text{mex}(0, 0, 3, 0, 3) = 1$, and we are done.
- If $k \equiv 1 \pmod 3$, then $\mathcal{G}(S_{1,1,1,k})$ is computed as $\text{mex}(1, 1, 1, 3, 1) = 0$, and we are done.
- If $k \equiv 2 \pmod 3$, then $\mathcal{G}(S_{1,1,1,k})$ is computed as $\text{mex}(2, 2, 0, 1, 0) = 3$, and we are done.

□

Lemma 23. *For all $k \geq 0$, we have $\mathcal{G}(S_{1,2,k}) = |S_{1,2,k}| \pmod 3$, i.e., $(\mathcal{G}(S_{1,2,k}))_{k \in \mathbb{N}} = \overline{120}$.*

Proof. We proceed by induction on k . The cases $k \leq 3$ are all consequences of Lemma 19 and 20. When $k \geq 4$, we can apply Lemma 2 since there are always exactly seven moves available, leading to $P_k, P_{k+2}, P_{k+3}, S_{1,1,k}, S_{1,2,k-1}, S_{1,2,k-2}$, and $S_{1,2,k-4}$. Indeed, the lemma can be applied with \mathcal{F} set to the set of all paths together with subdivided stars of Lemma 21 and subdivided stars $S_{1,2,k'}$ such as $k' < k$, so as to get the desired result by induction (with T in the statement of Lemma 2 set to 3 and $\alpha_i = i$ for $i \in \{0, 1, 2\}$). □

Lemma 24. *For all $k \geq 0$, we have $\mathcal{G}(S_{1,1,2,k}) = \begin{cases} 2 & \text{if } k \equiv 0 \pmod 3 \\ 3 & \text{if } k \equiv 1 \pmod 3 \\ 1 & \text{if } k \equiv 2 \pmod 3 \end{cases}$, i.e., $(\mathcal{G}(S_{1,1,2,k}))_{k \in \mathbb{N}} = \overline{231}$.*

Proof. The small cases $k \leq 3$ are all consequences of Lemma 20. When $k \geq 4$, there are always exactly six possible moves, leading to $S_{1,1,2,k-1}, S_{1,1,2,k-2}, S_{1,1,2,k-4}, S_{1,1,1,k}, S_{1,1,k}$, and $S_{1,2,k}$. By induction, and thanks to Lemma 21, 22 and 23, we then have:

- If $k \equiv 0 \pmod 3$, then $\mathcal{G}(S_{1,1,2,k})$ is computed as $\text{mex}(1, 3, 1, 1, 0, 1) = 2$, and we are done.
- If $k \equiv 1 \pmod 3$, then $\mathcal{G}(S_{1,1,2,k})$ is computed as $\text{mex}(2, 1, 2, 0, 1, 2) = 3$, and we are done.
- If $k \equiv 2 \pmod 3$, then $\mathcal{G}(S_{1,1,2,k})$ is computed as $\text{mex}(3, 2, 3, 3, 2, 0) = 1$, and we are done.

□

Note that none of the subdivided stars $S_{1,1,2,k}$ is a \mathcal{P} -position. We also need the following detailed analysis of the subdivided star $S_{3,3,3}$.

Lemma 25. *We have $\mathcal{G}(S_{3,3,3}) = \mathcal{G}(S_{2,2,2}) = 1$, $\mathcal{G}(S_{2,2,3}) = 2$, with the Grundy numbers of subdivided stars that are accessible from $S_{3,3,3}$ as in Figure 2.*

Proof. The proof is straightforward, and relies on Lemmas 19 and 20. Figure 2 details the computation of $\mathcal{G}(S_{3,3,3})$. □

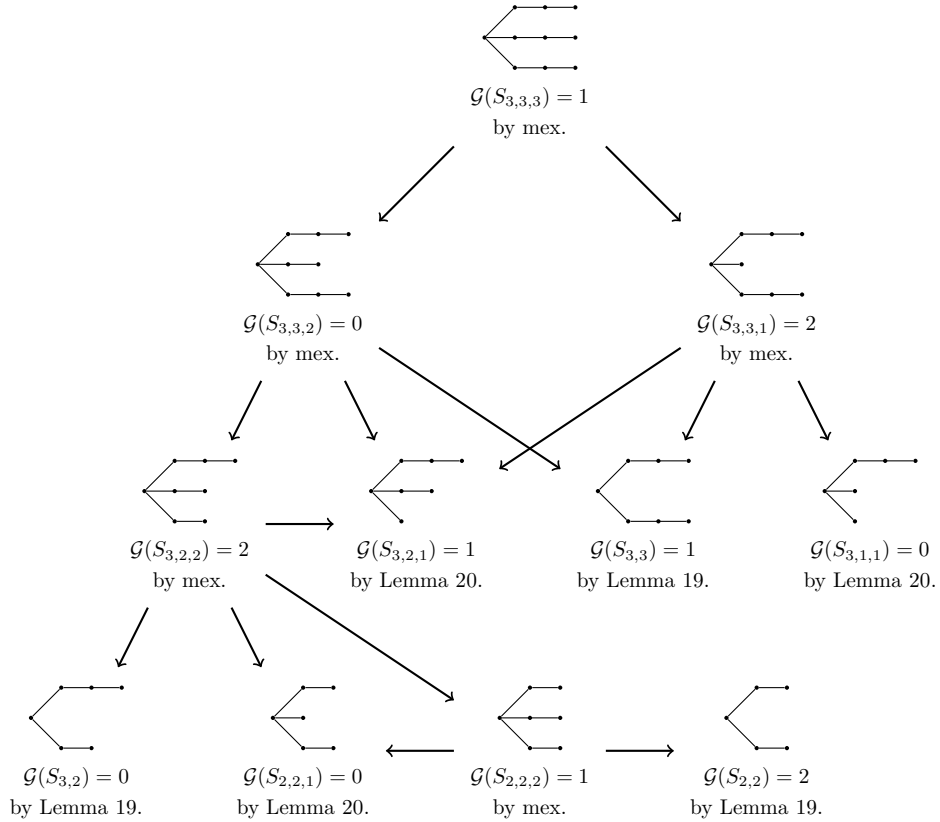

Figure 2: Analysis of $S_{3,3,3}$. The Grundy values are obtained using the mex rule and Lemmas 19 and 20.

Lemma 26. *For all $k \geq 0$, we have $\mathcal{G}(S_{2,2,k}) = |S_{2,2,k}| \bmod 3$, i.e., $(\mathcal{G}(S_{2,2,k}))_{k \in \mathbb{N}} = \overline{201}$.*

Proof. We proceed by induction on k . The cases $k \leq 3$ are consequences of Lemma 19, 20 and 25. When $k \geq 4$, there are always exactly five moves available, leading to $S_{2,2,k-1}$, $S_{2,2,k-2}$, $S_{2,2,k-4}$, $S_{1,2,k}$, and P_{k+3} . We then conclude by

induction and thanks to Lemma 2, since all these graphs (see Lemma 19 and 23) are such that $\mathcal{G}(G) = |G| \pmod 3$. \square

Lemma 27. *For all $k \geq 0$, we have $\mathcal{G}(S_{1,2,2,k}) = |S_{1,2,2,k}| \pmod 3$; in other words, $(\mathcal{G}(S_{1,2,2,k}))_{k \in \mathbb{N}} = \overline{012}$.*

Proof. We proceed by induction on k . The cases $k \leq 1$ are consequences of Lemma 20. For $k = 2$, three moves are available from $S_{1,2,2,2}$, leading to $S_{1,1,2,2}$, $S_{1,2,2}$, and $S_{2,2,2}$, and we conclude thanks to Lemma 20 and 26. For $k = 3$, five moves are available from $S_{1,2,2,3}$, leading to $S_{1,2,2,2}$, $S_{1,1,2,2}$, and $S_{1,1,2,3}$, $S_{1,2,3}$, and $S_{2,2,3}$, and we conclude thanks to Lemma 20 and 26. When $k \geq 4$, there are always exactly six moves available, leading to $S_{1,2,2,k-1}$, $S_{1,2,2,k-2}$, $S_{1,2,2,k-4}$, $S_{1,1,2,k}$, $S_{1,2,k}$, and $S_{2,2,k}$. We conclude by induction, and thanks to Lemma 23, 24, and 26, since we have:

- If $k \equiv 0 \pmod 3$, then $\mathcal{G}(S_{1,2,2,k})$ is computed as $\text{mex}(2, 1, 2, 2, 1, 2) = 0$, and we are done.
- If $k \equiv 1 \pmod 3$, then $\mathcal{G}(S_{1,2,2,k})$ is computed as $\text{mex}(0, 2, 0, 3, 2, 0) = 1$, and we are done.
- If $k \equiv 2 \pmod 3$, then $\mathcal{G}(S_{1,2,2,k})$ is computed as $\text{mex}(1, 0, 1, 1, 0, 1) = 2$, and we are done.

\square

Lemma 28. *For all $k \geq 0$, we have $\mathcal{G}(S_{1,1,1,1,k}) = |S_{1,1,1,1,k}| + 1 \pmod 3$, i.e., $(\mathcal{G}(S_{1,1,1,1,k}))_{k \in \mathbb{N}} = \overline{012}$.*

Proof. We proceed by induction on k . The case $k = 0$ is a consequence of Lemma 20. For $k = 1$, one move is available from $S_{1,1,1,1,1}$, leading to $S_{1,1,1,1}$, and we conclude again thanks to Lemma 20. For $k = 2$, three moves are available from $S_{1,1,1,1,2}$, leading to $S_{1,1,1,1,1}$, $S_{1,1,1,1}$, and $S_{1,1,1,2}$, and we conclude thanks to Lemma 20 (and thanks to the case $k = 0$ above). The case $k = 3$ is not harder: three moves lead to $S_{1,1,1,1,2}$, $S_{1,1,1,1,1}$, and $S_{1,1,1,3}$, and we can conclude thanks to Lemma 20 and thanks to the cases $k \leq 2$ above. When $k \geq 4$, there are always exactly four moves available, leading to $S_{1,1,1,1,k-1}$, $S_{1,1,1,1,k-2}$, $S_{1,1,1,1,k-4}$, and $S_{1,1,1,k}$. We conclude by induction, and thanks to Lemma 22, since we have:

- If $k \equiv 0 \pmod 3$, then $\mathcal{G}(S_{1,1,1,1,k})$ is computed as $\text{mex}(2, 1, 2, 1) = 0$, and we are done.
- If $k \equiv 1 \pmod 3$, then $\mathcal{G}(S_{1,1,1,1,k})$ is computed as $\text{mex}(0, 2, 0, 0) = 1$, and we are done.

- If $k \equiv 2 \pmod 3$, then $\mathcal{G}(S_{1,1,1,k})$ is computed as $\text{mex}(1, 0, 1, 3) = 2$, and we are done.

□

Note that Lemma 2 is not invoked in the two previous proofs. This is due to the cases $S_{1,1,2,k}$ and $S_{1,1,1,k}$, which appear in the general case $k \geq 4$, but do not satisfy the properties $\mathcal{G}(G) = |G| \pmod 3$ and $\mathcal{G}(G) = |G| + 1 \pmod 3$, respectively.

We are now ready to prove Theorem 18.

Proof of Theorem 18. The proof is similar to that of Theorem 16. We denote A (for Alice) the first player, and B (for Bob) the second player, and we will show by induction that for any subdivided star $S = S_{\ell_1, \dots, \ell_t, m}$ with $\ell_1, \dots, \ell_t, m \geq 0$, then $S + S'$ is always a \mathcal{P} -position, with S' defined as $S_{\ell_1, \dots, \ell_t, m+3}$.

Let $b(S)$ be the number of nontrivial branches of S , that is to say $b(S) = |\{i \mid \ell_i > 0\}|$ if $m = 0$ and $b(S) = |\{i \mid \ell_i > 0\}| + 1$ otherwise.

If $b(S) = 0$ then we are trivially done thanks to Lemma 19 since $S = P_1$ and $S' = P_4$.

If $b(S) = 1$, then we conclude again by Lemma 19 since S and S' are both paths.

If $b(S) \geq 2$, then several cases follow.

If A plays in S' so as to leave $S + S_{\ell_1, \dots, \ell_t, m+3-k}$, with $k \in \{1, 2, 4\}$, then B replies by taking $3 - k$ vertices in S' if $k \in \{1, 2\}$, so as to leave $S + S_{\ell_1, \dots, \ell_t, m} = S + S$, which is a \mathcal{P} -position, and if $k = 4$ then B replies by taking 1 vertex in S , so as to leave $S_{\ell_1, \dots, \ell_t, m-1} + S_{\ell_1, \dots, \ell_t, m-1}$, which is a \mathcal{P} -position.

If A plays elsewhere in S' , then B can always copy A's move on S . For instance, if A removes $k \geq \ell_1$ vertices in S' , so as to leave $S \cup S_{\ell_1-k, \dots, \ell_t, m+3}$, then B removes k vertices in S so as to leave $S_{\ell_1-k, \dots, \ell_t, m} \cup S_{\ell_1-k, \dots, \ell_t, m+3}$. When B replies by mimicking A's move on S , B manages to leave $T + T'$ to A, with $|T| < |S|$, and we thus can conclude by induction that this is a \mathcal{P} -position.

If A plays in S , then we have to be careful. If A's move does not involve taking the center of S , then we are done, since B is again always able to copy A's move in S' , so as to leave $T + T'$ to A, with $|T| < |S|$, and we again conclude by induction that this is a \mathcal{P} -position.

The tricky cases are the ones where A takes the center of S . Indeed, in this case, B can not always simply copy A's move in S' , and we have to carry a more detailed analysis. For instance, if $S = S_{1,1,1,2}$ and $S' = S_{1,1,1,2,3}$, and if A removes 4 vertices so as to leave $P_2 + S_{1,1,1,2,3}$, then B can not mimic A's move in S' since it would disconnect $S_{1,1,1,2,3}$, so as to leave $P_2 + P_2 + P_3$. In other words, A's move copied in S' is not always a legal move.

Let us assume now that A's move in S can not be copied by player B in S' . In this case, A was able to remove the centre of S , and this implies that S has at most 4 nontrivial branches, and that S' has at most one more nontrivial branch than S .

Note also that A removed strictly more than one vertex to S , and exactly $b(S) - 1$ branches of S (if A empties S then B can trivially copy A's move on S' so as to leave P_3). Three cases and several subcases follow. We will denote by k the number of vertices removed by A.

Case 1: $b(S) = 2$. Without loss of generality, let us assume $S = S_{\ell_1, \ell_2}$ with $1 \leq \ell_1 \leq \ell_2$. As in the case of Theorem 16, if there is a long enough branch in S (w.r.t the number of vertices removed by A), then we will proceed by a mirror argument, since S is actually a path $P_{\ell_1 + \ell_2 + 1}$. More precisely, if $k \leq \ell_2$, then we may consider A actually played so as to leave $S_{\ell_1, \ell_2 - k} + S'$, and in this case player B can copy A's move on S' , and we are done.

Let us assume now that $k > \ell_2$. If $k = 2$, then $S = S_{1,1}$, and we may have either $S' = S_{1,4} = P_6$ or $S' = S_{1,1,3}$. If $S' = S_{1,4} = P_6$, then A may remove 2 vertices from P_6 so as to leave $P_1 + P_4$, which is a \mathcal{P} -position. If $S' = S_{1,1,3}$, then A may remove 2 vertices from $S_{1,1,3}$ so as to leave $P_1 + S_{1,1,1}$, which is a \mathcal{P} -position since we know from Lemma 20 that $\mathcal{G}(S_{1,1,1}) = 1 = \mathcal{G}(P_1)$.

If $k = 4$, then there are several subcases.

- If $S = S_{1,2}$, then A leaves $\emptyset + S' = S'$ and we may have either $S' = P_7$ or $S' = S_{1,2,3}$. If $S' = P_7$, then A may remove 1 vertex from P_7 so as to leave P_6 , which is a \mathcal{P} -position. If $S' = S_{1,2,3}$, then A may remove 1 vertex from $S_{1,2,3}$ so as to leave P_6 , which is a \mathcal{P} -position.
- If $S = S_{1,3}$, then A leaves $P_1 + S'$ and we may have either $S' = P_8$ or $S' = S_{1,3,3}$. If $S' = P_8$, then A may remove 1 vertex from P_8 so as to leave $P_1 + P_7$, which is a \mathcal{P} -position. If $S' = S_{1,3,3}$, then A may remove 1 vertex from $S_{1,3,3}$ so as to leave $P_1 + S_{1,2,3}$, which is a \mathcal{P} -position thanks to Lemma 20.
- If $S = S_{2,2}$, then A leaves $P_1 + S'$ and we may have either $S' = P_8$ or $S' = S_{2,2,3}$. If $S' = P_8$, then A may remove 1 vertex from P_8 so as to leave $P_1 + P_7$, which is a \mathcal{P} -position. If $S' = S_{2,2,3}$, then A may remove 1 vertex from $S_{2,2,3}$ so as to leave $P_1 + S_{2,2,2}$, which is a \mathcal{P} -position thanks to Lemma 25.
- If $S = S_{2,3}$, then A leaves $P_2 + S'$ and we may have either $S' = P_9$ or $S' = S_{2,3,3}$. If $S' = P_9$, then A may remove 1 vertex from P_9 so as to leave $P_2 + P_8$, which is a \mathcal{P} -position. If $S' = S_{2,3,3}$, then A may remove 1 vertex from $S_{2,3,3}$ so as to leave $P_2 + S_{2,2,3}$, which is a \mathcal{P} -position thanks to Lemma 25.
- If $S = S_{3,3}$, then A leaves $P_3 + S'$ and we may have either $S' = P_{10}$ or $S' = S_{3,3,3}$. If $S' = P_{10}$, then A may remove 1 vertex from P_{10} so as to leave $P_3 + P_9$, which is a \mathcal{P} -position. If $S' = S_{3,3,3}$, then A may remove 1 vertex from $S_{3,3,3}$ so as to leave $P_3 + S_{2,3,3}$, which is a \mathcal{P} -position thanks to Lemma 25.

Case 2: $b(S) = 3$. Let us denote $S = S_{\ell_1, \ell_2, \ell_3}$. In this case, we must have $k = 4$. Two subcases follow.

- If $S = S_{1,1,\ell_3}$, then A leaves $P_{\ell_3-1} + S'$, and we may have $S' = S_{1,1,3,\ell_3}$, $S' = S_{1,1,\ell_3+3}$, or $S' = S_{1,4,\ell_3}$.
 - If $S' = S_{1,1,3,\ell_3}$, then B's answer depends on $\ell_3 \pmod 3$. If $\ell_3 \equiv 0 \pmod 3$, B may reply by taking 1 vertex in S' , so as to leave $P_{\ell_3-1} + S_{1,1,2,\ell_3}$. Indeed, from Lemma 24, we know that $\mathcal{G}(S_{1,1,2,\ell_3}) = 2 = \mathcal{G}(P_{\ell_3-1})$, thus $P_{\ell_3-1} + S_{1,1,2,\ell_3}$ is a \mathcal{P} -position. If $\ell_3 \equiv 1 \pmod 3$, B may reply by taking 2 vertices in S' , so as to leave $P_{\ell_3-1} + S_{1,1,1,\ell_3}$. Indeed, from Lemma 22, we know that $\mathcal{G}(S_{1,1,1,\ell_3}) = 0 = \mathcal{G}(P_{\ell_3-1})$, thus $P_{\ell_3-1} + S_{1,1,1,\ell_3}$ is a \mathcal{P} -position. If $\ell_3 \equiv 2 \pmod 3$, B may reply by taking 1 vertex in S' , so as to leave $P_{\ell_3-1} + S_{1,1,2,\ell_3}$. Indeed, from Lemma 24, we know that $\mathcal{G}(S_{1,1,2,\ell_3}) = 1 = \mathcal{G}(P_{\ell_3-1})$, thus $P_{\ell_3-1} + S_{1,1,2,\ell_3}$ is a \mathcal{P} -position.
 - If $S' = S_{1,1,\ell_3+3}$, then B removes 4 vertices from S' , so as to leave $P_{\ell_3-1} + P_{\ell_3-1}$, which is a \mathcal{P} -position.
 - If $S' = S_{1,4,\ell_3}$, then B removes 4 vertices from S' , so as to leave $P_{\ell_3-1} + P_{\ell_3+2}$, which is a \mathcal{P} -position.
- If $S = S_{1,2,\ell_3}$, then A leaves $P_{\ell_3} + S'$, and we may have $S' = S_{1,2,3,\ell_3}$, $S' = S_{1,2,\ell_3+3}$, $S' = S_{1,5,\ell_3}$, or $S' = S_{2,4,\ell_3}$. If $S' = S_{1,2,3,\ell_3}$, B can reply by taking 1 vertex in S' , so as to leave $P_{\ell_3} + S_{1,2,2,\ell_3}$, which is a \mathcal{P} -position. Indeed, from Lemma 27, we know that $\mathcal{G}(S_{1,1,2,\ell_3}) = \mathcal{G}(P_{\ell_3}) = \ell_3 \pmod 3$. If $S' = S_{1,2,\ell_3+3}$, then B may reply by removing 1 vertex from S' , so as to leave $P_{\ell_3} + P_{\ell_3+3}$, which is a \mathcal{P} -position. If $S' = S_{1,5,\ell_3}$, then B may reply by removing 1 vertex from S' , so as to leave $P_{\ell_3} + P_{\ell_3+6}$, which is a \mathcal{P} -position. Finally, if $S' = S_{2,4,\ell_3}$, then B may reply by removing 4 vertices from S' , so as to leave $P_{\ell_3} + P_{\ell_3+3}$, which is a \mathcal{P} -position.

Case 3: $b(S) = 4$. In this case, we must have $k = 4$ and $S = S_{1,1,1,\ell_4}$, and A leaves $P_{\ell_4} + S'$, with $S' = S_{1,1,1,3,\ell_4}$, $S' = S_{1,1,1,\ell_4+3}$, or $S' = S_{1,1,4,\ell_4}$. If $S = S_{1,1,1,3,\ell_4}$, then a good answer for B is then to remove 2 vertices from S' , so as to leave $P_{\ell_4} + S_{1,1,1,1,\ell_4}$, which is a \mathcal{P} -position, since we know from Lemma 28 that $\mathcal{G}(S_{1,1,1,1,\ell_4}) = \mathcal{G}(P_{\ell_4}) = \ell_4 \pmod 3$. If $S = S_{1,1,1,\ell_4+3}$, then B may remove 4 vertices from S' , so as to leave $P_{\ell_4} + P_{\ell_4+3}$, which is a \mathcal{P} -position. If $S = S_{1,1,4,\ell_4}$, then B may remove 4 vertices from S' , so as to leave $P_{\ell_4} + S_{1,1,\ell_4}$, which is a \mathcal{P} -position, since we know from Lemma 21 that $\mathcal{G}(S_{1,1,\ell_4}) = P_{\ell_4} = \ell_4 \pmod 3$. □

5. Conclusion

In this paper, we derived results for connected subtraction games in graphs. Our main results deal with graphs to which we append paths, for which we were able to derive a very general result showing that there is always ultimate periodicity, in the sense that, for any finite set L , there exists two integers k_0 and T such that

$$\mathcal{G}_L(G \overset{\bullet}{\underset{u}{\bullet}} \rightarrow P_{k+T}) = \mathcal{G}_L(G \overset{\bullet}{\underset{u}{\bullet}} \rightarrow P_k),$$

whenever $k \geq k_0$ (Theorem 1). Is it true that the period T is the same as the period of the game played on paths?

We then managed to prove pure periodicity results in some particular cases. We showed that, for some classes of graphs and sets L , equation $\mathcal{G}_L(G \overset{\bullet}{\underset{u}{\bullet}} \rightarrow P_{k+T}) = \mathcal{G}_L(G \overset{\bullet}{\underset{u}{\bullet}} \rightarrow P_k)$ holds starting from $n_0 = 0$. This is the case, for instance, for simple stars when playing $CSG(\{1, \dots, N\})$ (Proposition 8), for subdivided stars when playing $CSG(\{1, 2, 3\})$ or $CSG(\{1, 2, 4\})$ (Theorems 16 and 18).

However, even in graphs as structurally simple as subdivided stars, pure periodicity is not the general setting, even if the game is purely periodic when played in paths. We proved, for instance, in Theorem 10 that we only have ultimate periodicity in subdivided stars of type $S_{1,k,\ell}$ for the game $CSG(\{1, \dots, N\})$. For instance, as a corollary of Theorem 10, we have $\mathcal{G}(S_{1,2,8}) = 10$ whereas $\mathcal{G}(S_{1,2+9k,8}) = 6$ for all $k \geq 1$, for the game $CSG(\{1, \dots, 8\})$. Note that this game is purely periodic when played in paths, and that subdivided stars of the form $S_{1,k,\ell}$ can be seen as paths to which we attached a vertex. Hence there is a complexity gap in the computation of the Grundy values when considering subdivided stars instead of paths. This complexity gap between paths and stars is also illustrated by Observation 17, which states that, for subdivided stars – and even for stars – the Grundy sequence of $CSG(I_N \cup \{M\})$ may be different from the one of $CSG(I_N)$, for $M \not\equiv 0 \pmod{N + 1}$.
