Example (from last time)

$$A = \begin{bmatrix} -7 & 1 & 0 \\ 1 & -3 & 2 \\ 0 & 2 & -7 \end{bmatrix} :$$

$$\begin{vmatrix} -7 - \lambda & 1 & 0 \\ 1 & -3 - \lambda & 2 \\ 0 & 2 & -7 - \lambda \end{vmatrix}$$

$$= (-7 - \lambda)^{2}(-3 - \lambda) + 0 + 0 - 0 - 4(-7 - \lambda) - 1(-7 - \lambda)$$

$$= (-7 - \lambda)[21 + 10\lambda + \lambda^{2} - 5] = (-7 - \lambda)(\lambda^{2} + 10\lambda + 16)$$

$$= (-7 - \lambda)(\lambda + 2)(\lambda + 8)$$

$$= 0 \text{ when } \lambda = -7, -2, -8$$

Example (continued)

$$A = \begin{bmatrix} -7 & 1 & 0 \\ 1 & -3 & 2 \\ 0 & 2 & -7 \end{bmatrix} :$$
$$\lambda = -7 : \begin{bmatrix} 0 & 1 & 0 \\ 1 & 4 & 2 \\ 0 & 2 & 0 \end{bmatrix} \rightarrow \begin{bmatrix} 1 & 0 & 2 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix} : \begin{bmatrix} -2 \\ 0 \\ 1 \end{bmatrix}$$
$$\lambda = -2 : \begin{bmatrix} -5 & 1 & 0 \\ 1 & -1 & 2 \\ 0 & 2 & -5 \end{bmatrix} \rightarrow \begin{bmatrix} 1 & 0 & -1/2 \\ 0 & 1 & -5/2 \\ 0 & 0 & 0 \end{bmatrix} : \begin{bmatrix} 1/2 \\ 5/2 \\ 1 \end{bmatrix}$$
$$\lambda = -8 : \begin{bmatrix} 1 & 1 & 0 \\ 1 & 5 & 2 \\ 0 & 2 & 1 \end{bmatrix} \rightarrow \begin{bmatrix} 1 & 0 & -1/2 \\ 0 & 1 & -5/2 \\ 0 & 0 & 0 \end{bmatrix} : \begin{bmatrix} 1/2 \\ -1/2 \\ 1 \end{bmatrix}$$

<□ > < @ > < E > < E > E のQ @

Proposition

If $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k$ are eigvecs of A corresponding to <u>different</u> eigvals $\lambda_1, \lambda_2, \dots, \lambda_k$, then $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k$ are lin ind.

Proof.

As an eigvec, $\mathbf{v}_1 \neq \mathbf{0}$. WLOG, \mathbf{v}_k is the first one that is in span of earlier ones, say $\mathbf{v}_k = c_1 \mathbf{v}_1 + \cdots + c_{k-1} \mathbf{v}_{k-1}$. Multiply by A, multiply by λ_k and take difference:

$$\mathbf{0} = \sum_{i=1}^{k-1} c_i (\lambda_i - \lambda_k) \mathbf{v}_i \; .$$

All $(\lambda_i - \lambda_k)$'s are nonzero and some c_i is nonzero, say c_{k-1} , so

$$\mathbf{v}_{k-1} = \sum_{i=1}^{k-2} - rac{c_i(\lambda_i - \lambda_k)}{c_{k-1}(\lambda_{k-1} - \lambda_k)} \mathbf{v}_i \; ,$$

contradicting our choice of \mathbf{v}_k .

Example (resumed)

So as eigvecs corresponding to different eigvals,

$$\begin{bmatrix} -2\\0\\1 \end{bmatrix}, \begin{bmatrix} 1/2\\5/2\\1 \end{bmatrix}, \begin{bmatrix} 1/2\\-1/2\\1 \end{bmatrix}$$

are lin ind, and $S = \begin{bmatrix} -2 & 1/2 & 1/2\\0 & 5/2 & -1/2\\1 & 1 & 1 \end{bmatrix}$ is invertible.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Trace of a square matrix

The sum of the main diagonal entries of a square matrix is the *trace*. We have trace(A + B) = trace A + trace B, but NOT trace(AB) = (trace A)(trace B).

Who cares? Well, it provides a check on the eigenvalues:

det A = product of the eigvals of Atrace A = sum of the eigvals of A

Verifying the last claim

Consider characteristic polynomial

$$\begin{vmatrix} a_{11} - \lambda & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} - \lambda & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \dots & a_{nn} - \lambda \end{vmatrix} = (\lambda_1 - \lambda)(\lambda_2 - \lambda)\dots(\lambda_n - \lambda)$$

where λ_i 's are the eigvals.

Constant term, when $\lambda = 0$, is |A|, but it is also product of λ_i 's.

Coefficient of λ^{n-1} is $(-1)^{n-1}$ times the sum of the λ_i 's, but also:

The only term in the Big Formula that has λ^{n-1} in it is from the main diagonal — the rest have at least 2 factors of constants. And the coefficient of λ^{n-1} in $(a_{11} - \lambda)(a_{22} - \lambda) \dots (a_{nn} - \lambda)$ is $(-1)^{n-1}$ times the sum of the a_{ii} 's, i.e., the trace.

Example again

$$A = \begin{bmatrix} -7 & 1 & 0\\ 1 & -3 & 2\\ 0 & 2 & -7 \end{bmatrix}$$
, eigvals $-7, -2, -8$:

trace
$$A = -7 + (-3) + -7 = -7 + -2 + -8$$

det
$$A = (-7)^2(-3) + 0 + 0 - 0 - 4(-7) - 1(-7)$$

= -112 = (-7)(-2)(-8)

Surprise!

Because now we are trying to solve some polynomials (in λ) that are <u>not</u> linear, some roots may not be real:

Example

$$C = \begin{bmatrix} 5 & 7 \\ -3 & -4 \end{bmatrix}:$$

$$\begin{vmatrix} 5-\lambda & 7 \\ -3 & -4-\lambda \end{vmatrix} = (5-\lambda)(-4-\lambda) + 21$$

$$= 1-\lambda+\lambda^{2}$$

$$= 0 \text{ when } \lambda = \frac{1 \pm \sqrt{1-4}}{2}$$

$$= \frac{1 \pm i\sqrt{3}}{2}$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

The set $\mathbb C$ of complex numbers is also a field, so we can start taking "scalars" from there.

The best part is, a polynomial with coefficients from \mathbb{C} has all its roots in \mathbb{C} , and we can always factor it into linear factors.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Continuing example

$$\lambda = \frac{1+i\sqrt{3}}{2} : \begin{bmatrix} \frac{9-i\sqrt{3}}{2} & 7\\ -3 & \frac{-9-i\sqrt{3}}{2} \end{bmatrix} \rightarrow \begin{bmatrix} 1 & \frac{14}{9-i\sqrt{3}}\\ 0 & 0 \end{bmatrix}$$

Note
$$\frac{14}{0-i\sqrt{2}} = \frac{14(9+i\sqrt{3})}{81+3} = \frac{9+i\sqrt{3}}{6},$$

so a corr eigvec is
$$\begin{bmatrix} -\frac{9+i\sqrt{3}}{6}\\ 1 \end{bmatrix}$$
.

An eigvec corr to
$$\lambda = \frac{1-i\sqrt{3}}{2}$$
 must be $\begin{bmatrix} -\frac{9-i\sqrt{3}}{6} \\ 1 \end{bmatrix}$ — take

complex conjugates everywhere.

New World Order

Just as we can picture real scalars as points on a line, we can think of complex scalars as points on a plane: x + iy corresponds to the point (x, y). Complex numbers add like vectors, as usual. But multiplication is handier if we write complex numbers in "polar form": $r(\cos \theta + i \sin \theta)$, where r is the distance from the origin and θ is the angle with the positive real axis. (By a coincidence of Maclaurin series, we can abbreviate this to $re^{i\theta}$.)

$$r(\cos \theta + i \sin \theta)s(\cos \varphi + i \sin \varphi)$$

= $rs[(\cos \theta \cos \varphi - \sin \theta \sin \varphi) + i(\cos \theta \sin \varphi + \sin \theta \cos \varphi)]$
= $rs[\cos(\theta + \varphi) + i \sin(\theta + \varphi)]$

Thus, to multiply two complex numbers, multiply their distances from the origin and <u>add</u> their angles from the positive real axis. (This looks even easier in exponential notation: $(re^{i\theta})(se^{i\varphi}) = (rs)e^{i(\theta+\varphi)}$.)

Roots of Unity

Thus, in \mathbb{C} , there are *roots of unity* spaced evenly around the unit circle: $\omega_n^n = 1$

▲□▶ ▲圖▶ ★ 国▶ ★ 国▶ - 国 - のへで

Any point on the unit circle in the complex plane is $\cos \theta + i \sin \theta$, where θ is the angle to the positive real axis. So:

$$\omega_{2} = \cos \pi + i \sin \pi = -1$$

$$\omega_{4} = \cos(\pi/2) + i \sin(\pi/2) = i$$

$$\omega_{4}^{2} = \cos \pi + i \sin \pi = \omega_{2} = -1$$

$$\omega_{3} = \cos(2\pi/3) + i \sin(2\pi/3) = -\frac{1}{2} + i \frac{\sqrt{3}}{2}$$

$$\omega_{3}^{2} = \cos(4\pi/3) + i \sin(4\pi/3) = -\frac{1}{2} - i \frac{\sqrt{3}}{2}$$

$$\omega_{6} = \cos(\pi/3) + i \sin(\pi/3) = \frac{1}{2} + i \frac{\sqrt{3}}{2}$$

$$\omega_{6}^{2} = \omega_{3}$$

$$\omega_{6}^{3} = \omega_{2} = -1$$

$$\omega_{8} = \cos(\pi/4) + i \sin(\pi/4) = \frac{\sqrt{2}}{2} + i \frac{\sqrt{2}}{2}$$

There are corresponding ω_n^k for all n, k, but the sines and cosines aren't nice. (Well, ω_5 isn't too bad.)

$\mathsf{Eigstuff} \to \mathsf{Diagonalization}$

Theorem

Suppose the $n \times n$ matrix A has n lin ind eigvecs $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n$, with corr eigvals $\lambda_1, \lambda_2, \dots, \lambda_n$ respectively. Form the matrix Swith cols the \mathbf{v}_i 's in order, and the diagonal matrix Λ with main diagonal entries the λ_i 's in order. Then $A = S\Lambda S^{-1}$.

Proof.

First, *S* is invertible. We show $S^{-1}AS = \Lambda$, one column at a time: First column of *S* is **v**₁, and A**v**₁ = λ_1 **v**₁, and

$$S^{-1}\lambda_1 \mathbf{v}_1 = \lambda_1 (\text{first column of I}) = \begin{bmatrix} \lambda_1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} = \text{first column of } \Lambda \ .$$

Similarly for the other columns.

Therefore,

$$A = \begin{bmatrix} -7 & 1 & 0 \\ 1 & -3 & 2 \\ 0 & 2 & -7 \end{bmatrix}$$
$$= \begin{bmatrix} -2 & 1/2 & 1/2 \\ 0 & 5/2 & -1/2 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} -7 & 0 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & -8 \end{bmatrix} \begin{bmatrix} -2 & 1/2 & 1/2 \\ 0 & 5/2 & -1/2 \\ 1 & 1 & 1 \end{bmatrix}^{-1}$$
$$C = \begin{bmatrix} 5 & 7 \\ -3 & -4 \end{bmatrix}$$
$$= \begin{bmatrix} -\frac{9+i\sqrt{3}}{6} & -\frac{9-i\sqrt{3}}{6} \\ 1 & 1 \end{bmatrix} \begin{bmatrix} \frac{1+i\sqrt{3}}{2} & 0 \\ 0 & \frac{1-i\sqrt{3}}{2} \end{bmatrix} \begin{bmatrix} -\frac{9+i\sqrt{3}}{6} & -\frac{9-i\sqrt{3}}{6} \\ 1 & 1 \end{bmatrix}^{-1}$$

First Application of Eigstuff

Powers of diagonal matrices are easy:

$$\begin{bmatrix} -7 & 0 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & -8 \end{bmatrix}^{4} = \begin{bmatrix} (-7)^{4} & 0 & 0 \\ 0 & (-2)^{4} & 0 \\ 0 & 0 & (-8)^{4} \end{bmatrix}$$

So if we can diagonalize a matrix, then we can find its powers easily:

$$A = S\Lambda S^{-1},$$
 so
 $A^4 = (S\Lambda S^{-1})(S\Lambda S^{-1})(S\Lambda S^{-1})(S\Lambda S^{-1}) = S\Lambda^4 S^{-1}$.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Example 1

$$\begin{bmatrix} -7 & 1 & 0 \\ 1 & -3 & 2 \\ 0 & 2 & -7 \end{bmatrix}^{4} = \begin{bmatrix} -2 & 1/2 & 1/2 \\ 0 & 5/2 & -1/2 \\ 1 & 1 & 1 \end{bmatrix}$$
$$\begin{bmatrix} (-7)^{4} & 0 & 0 \\ 0 & (-2)^{4} & 0 \\ 0 & 0 & (-8)^{4} \end{bmatrix}$$
$$\begin{bmatrix} -2 & 1/2 & 1/2 \\ 0 & 5/2 & -1/2 \\ 1 & 1 & 1 \end{bmatrix}^{-1}$$

Example 2

More interesting: Because $\frac{1+i\sqrt{3}}{2} = \omega_6$ and $\frac{1-i\sqrt{3}}{2} = \omega_6^5$,

$$C=S\left[egin{array}{cc} \omega_6 & 0\ 0 & \omega_6^5 \end{array}
ight]S^{-1},$$
 so

$$C^{6} = S \begin{bmatrix} \omega_{6}^{6} & 0\\ 0 & \omega_{6}^{30} \end{bmatrix} S^{-1} = S \begin{bmatrix} 1 & 0\\ 0 & 1 \end{bmatrix} S^{-1} = I$$
$$C^{3} = -I$$

Because 1024 = 6(170) + 4 by long division, we have

$$C^{1024} = (C^6)^{170} C^3 C = I^{170} (-I) C = -C$$

٠

A Discrete Linear Process

Example

A gene can be in one of two forms, dominant A or recessive b; and an animal in which this gene appears can be one of three "genotypes": pure dominant AA, pure recessive bb, or hybrid Ab. Suppose we always mate females with <u>hybrid</u> males and keep the female offspring. In the long run, what will the distribution of genotypes in the population we keep?

Suppose the distribution was initially d_0 dominant, h_0 hybrid and r_0 recessive (d_0 , h_0 , r_0 fractions adding to 1). After one breeding season, the distribution is

$$d_{1} = \frac{1}{2}d_{0} + \frac{1}{4}h_{0}$$

$$h_{1} = \frac{1}{2}d_{0} + \frac{1}{2}h_{0} + \frac{1}{2}r_{0} \text{ or } \begin{bmatrix} d_{1} \\ h_{1} \\ r_{1} \end{bmatrix} = \begin{bmatrix} \frac{1}{2} & \frac{1}{4} & 0 \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \\ 0 & \frac{1}{4} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} d_{0} \\ h_{0} \\ r_{0} \end{bmatrix}$$

$$r_{1} = \frac{1}{4}h_{0} + \frac{1}{2}r_{0}$$

Write
$$\mathbf{f}_n = \begin{bmatrix} d_n \\ h_n \\ r_n \end{bmatrix}$$
 and $A = \begin{bmatrix} \frac{1}{2} & \frac{1}{4} & 0 \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \\ 0 & \frac{1}{4} & \frac{1}{2} \end{bmatrix}$

Then $\mathbf{f}_{n+1} = A\mathbf{f}_n$ for each n, and we are asking what \mathbf{f}_n approaches as $n \to \infty$. Using R, I can check

.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

$$A^{1024} = \begin{bmatrix} \frac{1}{4} & \frac{1}{4} & \frac{1}{4} \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \\ \frac{1}{4} & \frac{1}{4} & \frac{1}{4} \end{bmatrix}, \text{ so } \mathbf{f}_{1024} = \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ \frac{1}{4} \end{bmatrix}$$

(with some error so small that R won't show it to me), no matter what \mathbf{f}_0 was, because $d_0 + h_0 + r_0 = 1$.

But why did all the columns of A^{1024} come out the same?

$$\begin{vmatrix} \frac{1}{2} - \lambda & \frac{1}{4} & 0 \\ \frac{1}{2} & \frac{1}{2} - \lambda & \frac{1}{2} \\ 0 & \frac{1}{4} & \frac{1}{2} - \lambda \end{vmatrix} = (\frac{1}{2} - \lambda)(-\lambda + \lambda^2)$$

so eigvals of A are $\frac{1}{2}, 0, 1$. Suppose corresponding eigvecs are $\mathbf{u}, \mathbf{v}, \mathbf{w}$ respectively, a basis for \mathbb{R}^3 . So if

$$\begin{split} \mathbf{f}_0 &= a \mathbf{u} + b \mathbf{v} + c \mathbf{w} \ , \quad \text{then} \\ \mathbf{f}_{1024} &= A^{1024} \mathbf{f}_0 = a (\frac{1}{2})^{1024} \mathbf{u} + b (0)^{1024} \mathbf{v} + c (1)^{1024} \mathbf{w} \approx c \mathbf{w} \end{split}$$

Find **w**: When $\lambda = 1$,

$$\begin{bmatrix} -\frac{1}{2} & \frac{1}{4} & 0\\ \frac{1}{2} & -\frac{1}{2} & \frac{1}{2}\\ 0 & \frac{1}{4} & -\frac{1}{2} \end{bmatrix} \rightarrow \begin{bmatrix} 1 & 0 & -1\\ 0 & 1 & -2\\ 0 & 0 & 0 \end{bmatrix} : \begin{bmatrix} 1\\ 2\\ 1 \end{bmatrix} \text{ or } \begin{bmatrix} \frac{1}{4}\\ \frac{1}{2}\\ \frac{1}{4} \end{bmatrix}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Conclusion: If A is diagonalizable and 1 is the largest eigval of A in absolute value, then $A^n \mathbf{f}$ is going to approach an eigvec \mathbf{w} of A corresponding to 1, i.e., a *steady state:* $A\mathbf{w} = \mathbf{w}$. Because the columns of A^n are just A^n times the columns of I, each column of A^n will also go to such an eigvec.

Suppose the columns of A all add up to 1. Then the columns of A - I add up to 0, so A - I is singular; i.e., 1 is an eigval of A. If it's the largest in absolute value and the eigenspace corr to it has dim 1, then all the columns of A^n will go to the same vector, the eigvec with sum 1.

And that was true of
$$A = \begin{bmatrix} \frac{1}{2} & \frac{1}{4} & 0\\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2}\\ 0 & \frac{1}{4} & \frac{1}{2} \end{bmatrix}$$

If an $n \times n$ matrix A has n different eigvals, then each has an eigvec; these form a basis for \mathbb{R}^n or \mathbb{C}^n , and A is diagonalizable.

But if A has a <u>repeated</u> eigval, there may or may not be enough eigvecs to give a basis.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

Example $A = \begin{bmatrix} 3 & 0 \\ 0 & 3 \end{bmatrix}$ is diagonalizable: S = I, $\Lambda = A$. Char poly is $(3 - \lambda)^2$, with repeated root 3:

$$\left[\begin{array}{cc} 3-3 & 0 \\ 0 & 3-3 \end{array}\right] \rightarrow \left[\begin{array}{cc} 0 & 0 \\ 0 & 0 \end{array}\right] : \left[\begin{array}{c} 1 \\ 0 \end{array}\right] \text{ and } \left[\begin{array}{c} 0 \\ 1 \end{array}\right]$$

Eigspace corr to 3 is all of \mathbb{R}^2 , so we can pick a basis for \mathbb{R}^2 consisting of eigvecs of A.

Example $B = \begin{bmatrix} 3 & 1 \\ 0 & 3 \end{bmatrix}$ is not diagonalizable: Char poly is again $(3 - \lambda)^2$, with repeated root 3, and

$$\left[\begin{array}{cc} 3-3 & 1 \\ 0 & 3-3 \end{array}\right] \rightarrow \left[\begin{array}{cc} 0 & 1 \\ 0 & 0 \end{array}\right] : \quad \left[\begin{array}{c} 1 \\ 0 \end{array}\right]$$

Eigval 3 has algebraic multiplicity 2, but geometric multiplicity only 1. We can't make a basis of \mathbb{R}^2 consisting of eigvecs of *B*, so *B* isn't diagonalizable.
